OF
AGRICULTURAL RESEARCH, PUSA

INDEX

NAME INDEX

Abbott (A), Education for Industry and Commerce in England (*Review*), 477

Abdel Salam (Dr M M) Botrytis Disease of Lettuce, 653

Abe (S), Sex in the Myxomycetes, 952

Abel (Prof J), Transport of Tetanus Toxin to the Central Nervous System, 691

Abel (Dr J J), Poisons and Disease, 422

Abercromby (Hon Ralph), Weather the Nature of Weather Changes from Day to Day New edition, revised and largely rewritten by A H R Goldie (*Review*), 932

Achard (C), and L Binet, Effects of Sodium Thiosulphate on Poisoning by Potassium Cyanide, 390

Adair (G S), Physical Chemistry of the Proteins (*Review*), 511

Adams (Prof A S), [Prof L B Loeb and], The Development of Physical Thought a Survey Course of Modern Physics (*Review*), 594

Adams (Dr W S), Life on the Planets, 356

Adel (A), and Prof E F Barker, Vibrational Energy Levels of Hydrogen Cyanide, 29

Adler (A A) Active and Inactive Forms of the Hormone promoting Comb Growth, 798; P de Fremery, and Dr M Tausk, Progestin in Placental Extract, 293

Agarbiceanu (I I), Absorption of Iodine Vapour in the Presence of Foreign Gases, 38

Agnew (J A), award to, of the gold medal of the Institution of Mining and Metallurgy, 609

Ahmad (T), Chemotropic Response of a Chironomid Fly (*Forcipomyia* sp) to Petroleum Oils, 462

Aikawa (Dr H), Larval forms of some Brachyura (2), 184

Ainsworth Davies (Prof J R), [death], 558; [obituary article], 603

Albert I, King of the Belgians, and Progressive Science, 284

Aldous (C W) [G A Hankins and], Minimum dimensions of Test Samples for Brinell and Diamond Pyramid Hardness Tests, 470

Alexander (Prof S), Beauty and other forms of Value (*Review*), 928

Algar (J), and J P Flynn, A New Method for the Synthesis of Flavonols, 542

Ali (Barkat), Temperature of the Atmosphere in Northern India, 618

Alichanian (A J), [A J Alichanow, B S Dzelepow and], Energy Spectrum of Positive Electrons ejected by Radioactive Nitrogen, 950; A New Type of Artificial β Radioactivity, 871

Alichanow (Dr A), Positive Electrons from Lead ejected by γ Rays, 581

Alichanow (A J), A J Alichanian, and B S Dzelepow, A New Type of Artificial β Radioactivity, 871; Energy Spectrum of Positive Electrons ejected by Radioactive Nitrogen, 950

Allee (W C), Mass Physiology in Animals, 727

Allen (Prof G C), British Industries and their Organisation (*Review*), 153

Allison (Prof I S), [Prof W H Emmons, Prof G A Thiel, Prof C R Stauffer and], Geology, 275

Allmand [Bateman and], Photochemical Union of Hydrogen and Chlorine, 537

Alty (Prof T), and F J Wilson, Height of the Aurora in Canada, 687

Amaldi (E), and Prof E Segrè, Effect of Pressure on High Terms of Alkaline Spectra, 141

Amantea (G), Antineuritic Factor (B_1) and the Conception of the Beri Beri Quotient (*Qb*), 699

Amati (A), [G Mezzadroli and], Action of Certain Alkaloids on Invertase, 587; Action of Certain Alkaloids on the Metabolism of Glucides by *Aspergillus niger*, 391

Amiel (J), Action of Chlorates on Sulphur, Selenium and Tellurium, 735

Anastasiades (M), Mechanism of Rectification in Copper Sulphide-Magnesium Rectifiers, 114

Andant (A), P Lambert, and J Lecomte, Application of Diffusion Spectra (Raman Effect) and Absorption in the Infra-red to Distinguish between the Five Isomeric Hexanes, 847

Anderson (A B), C R Harington, and D M Lyon, Di-iodothyronine in Myxoedema, 107

Anderson (B W), and C J Payne, Liquids of High Refractive Index, 66

Anderson (Dr C D), The Positron, 313

Anderson (Dr E), Origin of the Angiosperms, 462

Anderson (Dr J S), [A King and], Chemical Calculations their Theory and Practice (*Review*), 369

Andrade (Prof E N da C), New Experimental Work in Sound, 70

Andreiev (N), Possibility of Observing Brownian Movement with the Naked Eye, 699

Andreitcheva (Mlle M), [G Bertrand and], Comparative Proportions of Zinc in Green and Etiolated Leaves, 114

Andrewes (Dr C H), [Dr P P Laidlaw, Dr W Smith and], Research on Influenza, 353

Andrews (E C), Origin of Modern Mountain Ranges 391

Andrieux (L), and M Dodero Electrolysis of Fused Silicates and the Preparation of Silicon and Silicides, 586

Antoniadi (E M), L'Astronomie egyptienne depuis les temps les plus reculés jusqu'a la fin de l'époque Alexandrine (*Review*), 593

Apert (Dr E), translated by Dr R W B Ellis, Infantilism (*Review*), 707

Appleton (Prof E V), Radio Exploration of the Ionosphere, 793

Arditti (R), System Cadmium Sulphate, Sulphuric Acid, Water, 39

Armstrong (Prof H E), Designation of Heavy Hydrogen, 173; Ethane from Acetic Acid, 379; The Roll-call of the Hydrogens (Hydranes), 538

Arnot (Dr F L), Collision Processes in Gases (*Review*), 275

Arragon (G), Acetylation of Sorbose in the Presence of Pyridine, 923

Asbach (H R), [C Bachem, Dr E Hiedemann and], New Methods for Direct Visualisation of Ultrasonic Waves and for the Measurement of Ultra-sonic Velocity, 176

Ashmore (S A), New Apparatus for Determining the Temperature of Crystallisation of Cocoa Butter, 846

Ashworth (Prof J H), and Dr F F Darling, Bibliography of the *Works of James Cossar Ewart*, 644

Ashworth (Dr J R), Smoke and the Atmosphere Studies from a Factory Town (*Review*), 362

Asinger (F), Nitration of 3 5-dichlorobenzaldehyde and 3 5-dichlorobenzoic acid, 39

Astbury (W T), Fundamentals of Fibre Structure (*Review*), 120 , and R Lomax, X Ray Photographs of Crystalline Pepsin, 795 , and R D Preston, A Mercury sealed Water cooled Rotating X Ray Target, 460

Aston (Dr F W), Calcium Isotopes and the Problem of Potassium, 869 , Constitution of Hafnium and Other Elements, 684 , Constitution of Dysprosium, Holmium, Erbium, Thulium, Ytterbium and Lutecium, 327

Astor (Viscount), and Dr K A H Murray, The Planning of Agriculture (*Review*), 360

Atkins (Dr. W R G), [H H Poole and], Measurements of the Brightness of Various Parts of the Sky by Means of a Rectifier Photoelectric Cell, 38

Atwood (Dr W W), elected president of the Association of American Geographers 135

Audas (J W), Australian Oaks , their Economic Value, 536

Audubert (R), and Mlle Geneviève Lebrun, Influence of the Intensity of the Light on Photovoltaic Phenomena, 586 , and J Roulleau, Influence of Water in Certain Rectifying Contacts, 427

Auger (P), On the γ rays produced by the Passage of Neutrons through Hydrogenated Substances, 427 , et L Leprince Ringuet, Variation du Rayonnement cosmique suivant la latitude, 138 , Variation of the Cosmic Radiation between the Latitudes 45° N and 38° S , 39

Avebury (Lord), (1834-1913), 632

Awati (P R), and D S Deshpande, Reproductive Apparatus of *Thalassema*, 68

Awbery (J H), [Dr E Griffiths and], Pipe Heaters and Coolers, 32

Ayers (Dr H), [death], 17

Aynsley (E E), and Dr P L Robinson, Influence of Oxygen, Sulphur Dioxide and Moisture on the Homogeneous Combination of Hydrogen with Sulphur, 723

Babbitt (J D), [Dr K Mendelssohn and], Persistent Currents in Supraconductors, 459

Bach (A), Z Ermolieva, and M Stepanian, Fixation of Atmospheric Nitrogen by Means of Enzymes extracted from *Azotobacter*, 699

Bachem (C), Dr E Hiedemann, and H R Asbach, New Methods for Direct Visualisation of Ultra sonic Waves and for the Measurement of Ultra-sonic Velocity, 176

Baiersdorf (G), Limiting Proportions of Cadmium and Palladium Detectable Spectroscopically in Silver, 808

Bailey (Prof E B), West Highland Tectonics, 262 , and W J McCallien, Metamorphic Rocks of North-East Antrim, 542

Bailey (K C), [T. N Richardson and], Oxidation of Hydrazine by Potassium Ferricyanide, 698

Bailey (L H), The Cultivated Conifers in North America comprising the Pine Family and the Taxads Successor to the Cultivated Evergreens (*Review*), 9

Bailey (Prof V A), Interaction of Radio Waves, 869 , and Dr D F Martyn, Interaction of Radio Waves, 218

Bain (Dr W A), appointed lecturer in physiology in Leeds University, 504

Baker (E C Stuart), The Nidification of Birds of the Indian Empire Vol 2 (*Review*), 591

Baker (Sir Herbert), Symbolism in Art, 56

Baker (Prof H F), Principles of Geometry Vol 5 Analytical Principles of the Theory of Curves (*Review*), 155

Baker (Dr [illegible] R), and Prof J B S Haldane, Biology in Everyday Life (*Review*), 742

Balachnovskij (S), Problem of Carotine in the Organism, 699

Baldwin (Stanley), Industrial Research and the State, 523

Balfour (H), Lower Palæolithic 'Cleavers', Northern Nigeria, 535

Balfour Browne (Prof W A F), elected president of the Royal Microscopical Society, 136

Ball (Dr J), Qattara Depression and Water Power, 136

Ball (S C), Jungle-Fowls from the Pacific Islands, 180

Balla (E), [C Prévost, P Donzelot and], The Raman Effect, Molecular Refraction and Constitution, 735

Ballantine (S), Piezo-Electric Loud Speaker, 184

Balls (E K), Plant Collecting in Persia, 324

Baly (Prof E C C), and Dr L B Morgan, Kinetics of Photosynthesis and Allied Processes, 414

Banachiewicz (T), A Problem of Geophysics, 587

Bancroft (Dr H), External Leaf-characters of the Cricket-Bat and other Willows, 104

Bancroft (T L), Rearing of *Ceratodus*, 340

Banderet (E), Formation of Liesegang Rings by Electrolysis, 623

Banerjee (S), [Prof K S Krishnan and], Crystal Structure of 1, 3, 5 Triphenylbenzene, 497

Banerji (Prof A C), Nuclear Structure γ Ray Fission, and the Expanding Universe, 984

Banerji (S K), and M D Manohar, Artificial Vibrations of the Ground, 69

Bankart (A S B), Manipulative Surgery (*Review*), 516

Bannister (F A), [M H Hey and], Studies on the Zeolites (7), 541

Barbieri (G A), New Type of Complex Compounds of Bivalent Silver, 115

Barcinskij (B), Germination of the Seeds of *Orobanche cumana*, 995

Bardke (Prof P), translated, with additions and revisions by Prof Bardke, by H Kenney, Technique of Modern Welding (*Review*), 631

Barker (Prof E F), [A Adel and], Vibrational Energy Levels of Hydrogen Cyanide, 29

Barker (Dr M L), Basic German for Science Students With Vocabulary and English Translations of the German Passages (*Review*), 371

Barkhausen (Prof H), Lehrbuch der Elektronen-Rohren und ihrer technischen Anwendungen Band 2 Verstärker Vierte Auflage (*Review*), 888

Barlow (W), [death], 351 , [obituary article], 637

Barmenkov (J), [V Novikov, A. Gretchushnikov, A Nosov and], Process of Assimilation and Formation of Cautchouc in Tau sagiz, 227

Barnes (T Cunliffe), [E J Larson and], Parasitism in Heavy Water of Low Concentration, 873

Baroni (A), Lithium Alloys (2), 227 , Mixed Sulphonic Anhydrides (1), 115

Barr (G), and A L Thorogood, Determination of small Quantities of Fluorides in Water, 658

Barrett (Sir James W), A Tame Platypus, 260 , Causes of Blindness, 828 , Emigration Schemes in Australia, 243

Bartlett (M S), awarded a Rayleigh prize of Cambridge University, 469

Barton Wright (E), and A M McBain, Possible Chemical Nature of Tobacco Mosaic Virus, 260

Bastien (P), Existence of Three Allotropic Varieties of Calcium, 623 , [A Portevin and], Castability of Ternary Alloys, 471

Bastisse (E), [A Demolon and], Influence of the Anions on the Fixing and Mobilisation of Phosphoric Acid in Soils, 39

Basu (Dr N K), Vitamins from Egg Yolk and Fish Oil 262

Bateman (Dr J B), Mitogenetic Radiation and Bioluminescence, 860

Bateman and Allmand, Photochemical Union of Hydrogen and Chlorine, 537

Bathe (G), The Dredging Machine of Oliver Evans, 489

Bather (Dr F A), [death], 441 , [obituary article], 485 Uniformity in Bibliographic Particulars, 495

Baudouin (M.), Age at which Birds can Migrate, 427
Baur (Prof. E.), [death], 17; [obituary article], 239
Bauschinger (Johann), Centenary of the Birth of; Work of, 862
Bavink (B.), translated by H. S. Hatfield, Science and God (*Review*), 857
Baxter [Brentano, Cotton and], New Method of Photographic Photometry, 466
Baxter (G. P.), and J. S. Thomas, Atomic Weight of Cæsium, 953
Beach (D. M.), Phonetics of the Hottentot Language, 339
Beals (R. L.), Acaxee of Ancient Mexico, 143
Beams, Cold Emission from Liquid Mercury, 144
Beavis (E. A.), Neon Signs, 206
Beccari (late Dr. O.), revised and edited by Prof. U. Martelli, Asiatic Palms—Corypheæ (*Review*), 122
Beck (C.), Recent Advances in Microscopy, 286
Beck (G.), and Dr. K. Sitte, β emission of Positive Electrons, 722
Beck (H. C.), and Prof. C. G. Seligman, Barium in Ancient Glass, 982
Bedford (L. H.), and O. S. Puckle, A Velocity-Modulation Television System, 263
Bedford (R.), Surface Markings of the Henbury Meteorites, 575
de Beer (Dr. G. R.), [Prof. J. S. Huxley and], The Elements of Experimental Embryology (*Review*), 890
Beevers (C. A.), and H. Lipson, Crystal Structure of Copper Sulphate, 215; Crystal Structure of Copper Sulphate Pentahydrate, $CuSO_4.5H_2O$, 922
Bell (Prof. E. T.), Numerology (*Review*), 80
Bell (Dr. Julia), Heredity of Aniridia, 574
Bell (Dr. J. Mackintosh), [death], 523
Bell (Mary), [G. F. Hull, S. E. Green and], Pressure of Radiation, 958
Bell (R. P.), Acid Catalysis in Non-Aqueous Solvents, 333; and J. H. Wolfenden, Electrolytic Concentration of Diplogen, 25
Bellamy (Miss Ethel), presented with an honorary degree by Oxford University, 224
Bellerby (Dr. C. W.), A Rapid Test for the Diagnosis of Pregnancy, 494
Bellerby (J. R.), The Conflict of Values (*Review*), 778
Belton (J. W.), Kinetic Interpretation of the Activity Coefficients of Non-Electrolytes, 543
Bennett (M. G.), Condensation of Water in the Atmosphere, 915
Berg (Dr. L.), The Human Personality (*Review*), 374
Berg (Dr. W. F.), Plasticity of Bismuth due to Occluded Gas, 831
Berget (Baron Alphonse), [death], 320
Bernal (J. D.), and Miss D. Crowfoot, X-Ray Photographs of Crystalline Pepsin, 794
Bernfeld (A. J.), awarded a Dunn Exhibition in Physiology at Middlesex Hospital Medical School, 805
Bernheimer (W.), Intensity of Ultra-violet Solar Radiation (λ 3200) between April 1925 and June 1933, 427
Berridge (W. S.), All about Fish and Other Denizens of the Seas and Rivers (*Review*), 235
Berry (A. J.), appointed lecturer in Chemistry in Cambridge University, 881
von Bertalanffy (L.), translated and adapted by J. H. Woodger, Modern Theories of Development; an introduction to Theoretical Biology (*Review*), 123
Bertarelli (Prof. E.), Irradiated Yeast and Rickets, 838
Bertolini (Fausta), Teeth of Selachii in Relation to Nutrition, 587
Bertrand (G.), and Mlle. M. Andreitcheva, Comparative Proportions of Zinc in Green and Etiolated Leaves, 114; and P. Serbescu, Does the Daily Injection of Small Quantities of Aluminium favour Cancer? 770; Toxicity of Aluminium according to its Mode of Entrance to the System, 506
Besterman (T.), A Bibliography of Sir James George Frazer, O.M. (*Review*), 857; and O. Gatty, Investigation of Paraphysical Phenomena, 569
Bethe (Dr. H.), and R. Peierls, The "Neutrino", 532; 689
Bethe (Dr. H. A.), Atomic Collisions (*Review*), 363
Betim (A.), Kinematic Method of Quantitative Spectrum Analysis, 507
Beutel (E.), H. Haberlandt, and A. Kutzelnigg, Coloration of Marble in Iodine Vapour and the Nature of the Polished Layers, 428; Coloured Bromine Sorbates, 848
Bewley (Dr. W. F.), Practical Methods of Soil Heating, 332
Bhaduri (J. Lal), [Dr. Baini Prashad and], The Pearl Oysters of Indian Waters, 652
Bhattacharya (A. K.), [Prof. N. R. Dhar, S. P. Tandon, N. N. Biswas and], Photo-Oxidation of Nitrite to Nitrate, 213
Bidou (G.), Protractor with Index, 808
Biebl (R.), Action of α rays on the cells of *Bryum capillare*, 39
Bigelow (Prof. R. P.), De Causis Plantarum, 951
Biggs (H. F.), The Electromagnetic Field (*Review*), 372; [obituary], 93
Binder (O.), Action of Aqueous Solutions of Copper Sulphate on Cupric Hydroxide, 543
Binet (L.), [C. Achard and], Effects of Sodium Thiosulphate on Poisoning by Potassium Cyanide, 390
Binney (Commdr. R. D.), awarded a Thomas Gray prize of the Royal Society of Arts, 325
Birge (Prof. R. T.), The Value of *e/m*, 648
Bisby (G. R.), M. C. Jamieson, and M. Timonin, Fungi found in Butter, 68
Bisko (J.), [J. Zellner and], Contemporary Plant Chemistry (25), 268
Biswas (N. N.), [Prof. N. R. Dhar, S. P. Tandon, A. K. Bhattacharya and], Photo-Oxidation of Nitrite to Nitrate, 213
Black (Prof. Davidson), Recent Discoveries at Choukoutien, 89; [death], 441; [obituary article], 521; awarded the Elliot medal of the U.S. National Academy of Sciences, 788
Black (M.), appointed demonstrator in Geology in Cambridge University, 844
Blacker (Dr. C. P.), Human Values in Psychological Medicine (*Review*), 400
Blackett (Prof. P. M. S.), Cosmic Rays, 640; [Dr. J. Chadwick, G. Occhialini and], Production of Positive Electrons, 426; 765
Blackman (Dr. A. M.), Prof. F. Ll. Griffith, 556
Blacktin (Dr. S. C.), Periodic Structure in Ice, 613
Blaker (G. B.), Decrease of the Barn Owl in England and Wales, 768
Blakeslee (A. F.), [J. L. Cartledge and], Mutation Rate increased by Ageing Seeds as shown by Pollen Abortion, 960
Blandford (Henry Francis), Centenary of the birth of, 824
Blaringhem (L.), 'Fever' in *Arum*, 151
Bledisloe (Lord), Agricultural Education in New Zealand, 525; Research and Industry in New Zealand, 562
Blekslev (A. E. H.), Loss of Mass in Binary Systems, 613
Bligh (N. M.), A Panorama of Physics (*Review*), 594
Bloch (Dr. L.), Précis d'électricité théorique. Deuxième édition (*Review*), 551
Blondel (A.), Terminology in New Discoveries, 151; Use of Headlamps on Motor-cars with a Yellow Beam, 807
Blue (R. W.), [Dr. G. H. Dieke and], Spectrum of the HD- and D_2-Molecules, 611
Blum (H. F.), and C. R. Spealman, Sunlight and Death of Snakes, 143
Blumenthal (M.), [M. Centnerszwer and], Formation and Dissociation of the Alkaline Peroxides, 587
Boerema (Dr. J.), Rainfall in Netherlands Indies, 537
Bogitch (B.), Preparation of Ferrochrome in the Electric Furnace, 114
Bohr (Prof. N.), Atomic Theory and the Description of Nature. I: Four Essays, with an Introductory Survey (*Review*), 962
Bok (Dr. B. J.), Apparent Clustering of Galaxies, 578
Bolliger (A.), Volumetric Determination of Methylene Blue and Picric Acid, 151
Bond (Dr. W. N.), Value of *e/m*, 327

Bone (Prof W A), Speed of 'Uniform Movement' of Flame in Mixtures of Carbon Monoxide and Oxygen, 257
Bonham (H J), Aids to Botany (*Review*), 968
Bonhoeffer (Prof K F), und Dr P Harteck, Grundlagen der Photochemie (*Review*), 309
Bonino (G. B), and G Centola, Theory of Concentrated Solutions of Strong Electrolytes, 391
Bonnefoi (A), [G Sandor, J J Pérez and], Precipitation of the Proteins by Neutral Salts, 39
Bonnier and Moynot, Possible Consequences of the Use, in Internal Combustion Engines, of Hydrocarbons with a High Antidetonating Value, 114
Bontch-Bruewitch (Prof M A), Ionospheric Measurements in the Polar Regions, 175
Boone (L), Invertebrates from the Vanderbilt Museum, 535
Booth (E), An Elementary Introduction to Physics Descriptive, Experimental and Historical (*Review*), 551
Borchgrevink (C. E), [death], 639 , [obituary article], 750
Borel (Prof. E.), Probability of Series of Rainy Days or of Fine Weather, 74
Born (Prof Max), Cosmic Rays and the New Field Theory, 63 , elected an honorary member of the Academy of Sciences of the U S S R , 528 , title of Stokes lecturer in Mathematics conferred upon by Cambridge University, 957
Bose (A), Weiss Constant of Paramagnetic Ions in the *S* State, 213
Bose (Prof D. M), and P. K Raha, Influence of Light on Paramagnetic Susceptibility, 258
Boswell (Prof. P G H), Age of Sub Crag Implements, 331
Bouget (J), [C Dauzère and], Variations of the Conductivity of the Air in Caves, 471
Boulenger (E G), The Aquarium (*Review*), 235
Bourbon Parma (Prince Sixtus of), [death], 487
Boveri (Margaret), Personal Reminiscences of W C Röntgen (chapter in Dr O Glasser's Wilhelm Conrad Röntgen and the Early History of the Roentgen Rays) (*Review*), 511
Bowden (Dr E), and F W Main, The Gas Pressure Cable, 109
Bowden (F P), and S D D Morris, Physico-chemical Studies of Complex Organic Molecules (2), 698 , and Dr C P Snow, Physico chemical Studies of Complex Organic Molecules (1), 698
Bowen (E J), and H W Thompson, Photochemistry and Absorption Spectrum of Acetone, 571
Bowman (J), Consumption, Misuse and Waste of Water, 991
Boyland (Mrs), awarded a scholarship by the Cancer Hospital (Free), 136
Boyle (E), A Provitamin A other than Carotene ? 798
Boys (Dr C V), My Recent Progress in Gas Calorimetry (Guthrie lecture), 710 , work of, 677
Boys (S F), Optical Rotatory Power (1 and 2), 302
Bradford (B W), [Prof G I Finch and], Electrical Condition of Hot Surfaces (6), 302
Bradley (A. J), and J W Rodgers, Crystal Structure of the Heusler Alloys, 390 , 877
Bragg (Sir William), Liquid Crystals, 441, 445 , Refrigeration, 715 , The Universe of Light (*Review*), 549
Brambell (Prof. F W R), and H A Cole, Occurrence of an Enteropneust in Wales, 913
Bramley (A), Radiation and Ionisation produced by High Energy Electrons, 259
Brammall (A), [B Ramo Rao and], Cordierite in the Dartmoor Granite, 541
Branas (J). and J Dulac, Mode of Action of Copper Mixtures, 303
Brasnett (N V), State Forests, Forest Rights and Privileges of Local Inhabitants in Uganda, 619
Brauman (P), Some Organic Compounds of Vanadyl, 807
Brazier (C E), and Eblé, Temperature of the Air in the neighbourhood of the Soil, 187
Brearley (H), Steel Makers (*Review*), 50
Breazeale (L), [W P Stockwell and], Arizona Cacti, 500
Breder (C M), European Bitterling Spawning in American Mussels, 261
Brenchley (Dr. Winifred E), Dr Lilian Clarke, 439
Brentano, Baxter and Cotton, New Method of Photographic Photometry, 466
Breuil (Abbé H), Acceptance of the Presidency of the Prehistoric Society of East Anglia, 756
Brickwedde (F G), [Prof H C Urey, G M Murphy and], Designation of Heavy Hydrogen, 173
Briggs (Barbara), British Trees Second Series (*Review*), 84
Bright (N F H), and Prof W E. Garner, Rate of Nucleation of Copper Sulphate in Vacuum, 570
Brightman (R), Towards a Planned Society (*Review*), 477 , Industry and Leadership (*Review*), 628
Brindley (Dr W H), Ernst Haeckel, 331
Briscoe (Prof H. V A), Recent Advances in Chemistry, 70
British Drug Houses, Ltd , Catalogue of B D H Fine Chemical Products, 22
Broad (Dr. C D), Examination of McTaggart's Philosophy, Vol 1 (*Review*), 123
de Broglie (Maurice, Duc), elected to a seat in the Académie Française, 829
Bromley (H A), Static Charge on a Galvo-Millivoltmeter, 700
Broniewski (W), and K. Wesolowski, Structure of the Gold-Copper Alloys, 427
Brons (F), [Prof D Coster and], Predissociation in the Upper Level of the Ångström Bands of Carbon Monoxide, 140
Brooke (Rajah, Sir Charles), gift to the Imperial Forestry Institute, Oxford, 829
Brooks (Dr C E P), Variation of the Annual Frequency of Thunderstorms in relation to Sunspots, 506
Brouwer (D), [E W Brown and], Tables for the Development of the Disturbing Function with Schedules for Harmonic Analysis (*Review*), 369
Brown (C H), Meteorology for Masters and Mates Seventh edition (*Review*), 780
Brown (E W), and D Brouwer, Tables for the Development of the Disturbing Function with Schedules for Harmonic Analysis (*Review*), 369
Brown (Prof E W), and Prof C A Shook, Planetary Theory (*Review*), 740
Brown (Ida A), Geology of the South Coast of New South Wales, with Special Reference to the Origin and Relationships of the Igneous Rocks, 76
Brown (Dr J Coggin), Geography of Asia (*Review*), 361 , Small Sand Craters of Seismic Origin, 295
Brown (Nellie A), Root and Crown Rot of Peonies, 465
Brown (Dr W), Modern Science and the Possibility of Survival, 95 , The Theory of Two Factors versus the Sampling Theory of Mental Ability, 724
Bruce (late Dr J C), The Handbook to the Roman Wall a Guide to Tourists traversing the Barrier of the Lower Isthmus Ninth edition (*Review*), 48
Bruce (R G), appointed Naturalist-in charge of the Port Erin Marine Biological Station, 993
Bruckshaw (J McGarva), Instrument for Electrical Prospecting by the Inductive Method, 622
Bruges (W E), Importance of Deep Borehole Surveying, 790
Brun (P), Volume Variations of Mixtures of Water, Ethyl Alcohol, Ether, 187
Brunner (O), and F Grof, Synthesis of 1-ethyl 6 methyl- and 1-ethyl-7 methyl-naphthalene, 427 , and Gertrud Wiedemann, Components of Hornbeam Bark, 39 , Chemistry of Bark Substances (2), 427 , *p*-Methoxy and 3 : 4-dimethoxy-phenylurethanes, 39
Brunovsky (B), [W Venadsky, C Kunaševa and], γ-Mesothorium in *Lemna*, 151
Brunt (D), appointed professor of Meteorology at Imperial College—Royal College of Science, 336 , Possibility of Condensation by Descent of Air, 658
Buchanan (Sir George), retirement of , work of, 242
Buchanan-Riddell, Bt. (Sir Walter P), [death], 901
Buckland (Prof W), one hundred and fiftieth anniversary of the birth of, 353
Buckley (H), Colour Photometry, 333

Budgett (H. M.), Hunting by Scent (*Review*), 548
Bulman (Dr. O. M. B.), appointed lecturer in Geology in Cambridge University, 844
Bunyard (E. A.), The Introduction of Vegetables, 527
Burbidge, Action of β and γ rays on Rock Salt Crystals, 501
Burch, A New Test for Large Mirrors, 693
Burgess (M. J.), and Prof. R. V. Wheeler, Carbon Dioxide to Prevent Ignition of Firedamp by Sparks, 109
Burhop (E. H. S.), [H. M. Taylor and], Inner Conversion in X Ray Spectra, 531
Burkitt (Prof. A. N.), Some Aspects of the Vertebrate Brain, 943
Burlot (E.), Tendency to Destruction of Explosives by Inflammation in a Vacuum, 39
Burne (R. H.), retirement of, from the physiological curatorship of the Royal College of Surgeons' Museum, work of, 752
Burrard, (Col. Sir Sidney), Ground Levels in Bihar in relation to the Earthquake of January 15, 1934, 582
Burstein (R.), and P. Kashtanov, Activated Adsorption and Para Ortho Hydrogen Conversion on Charcoal, 571

Calcite, Thermal Expansion of, Measured with the X-Rays, J Weigle and H Saini, 847
Calcium: Isotope with Mass 41 and the Radioactive Half-period of Potassium, Prof J Kendall, W W Smith and T. Tait, 613, Isotopes and the Problem of Potassium, Dr. F W Aston, 869, Silicide, Preparation of, by High Temperature Electrolysis, M. Dodero, 959; Sulphate Hemihydrate, Dr W A Caspari, 648, Three Allotropic Varieties of, Existence of, P Bastien, 623
Calcutta, All-India Institute of Hygiene and Public Health, Dr. H. E C Wilson appointed professor of Biochemistry and Nutrition at the, 265
California, Mammals of, Dr J Grinnell, 30
Callender's New High-voltage Research Laboratories, 954
Cambridge University: Prof W Heisenberg appointed Rouse Ball lecturer for 1933–34, Prof J B Buxton elected a professorial fellow of Queen's College, 185, Abstracts of Dissertations approved for the Ph D, M.Sc and M Litt degrees, 1932-33, 208, Dr P E Vernon appointed Pinsent-Darwin student J W F. Rowe elected a fellow of Pembroke College, 265; appointment of Dr R Stoneley and Dr H M Taylor as University lecturers in Mathematics, Dr A H Gardiner appointed Frazer lecturer for 1934–35, Prof E. B Verney appointed Shield reader in Pharmacology, 424, J Yudkin appointed Benn W Levy research student in biochemistry, award of Smith's prizes to K Mitchell and A J. Ward, and Rayleigh prizes to M S Bartlett and C. G Pendse, grants from the Worts fund and the Balfour fund, 469, Dr. W A H. Rushton appointed lecturer in physiology, O A Trowell demonstrator in physiology, and Dr. H N. Green demonstrator in pathology, 504, Mary Somerville at, 585, Solar Physics Observatory 21st Annual Report, 644, award of the Sheepshanks Exhibition to C. G. Pendse, 657, R E Priestley appointed a professional fellow of Clare College, 733, A. V. Stephens elected a fellow of St John's College, 769; a lectureship in Forest Botany recommended, 805; Dr. O. M. B. Bulman appointed lecturer in geology, M Black demonstrator in geology, Dr G. N. Myers demonstrator in pharmacology and Dr H A. Krebs demonstrator in biochemistry, 844, A. J. Berry appointed lecturer in chemistry, Dr. C. P. Snow demonstrator in chemistry, and J A Ramsay demonstrator in Experimental zoology, 881, J. H. Driberg appointed lecturer in anthropology, Dr. S. Dickinson lecturer in mycology in the department of Agriculture, W. J. Dowson lecturer in mycology in the department of Botany, and Dr. H. Godwin lecturer in botany; Dr O. Tausky and Dr C. Leubuscher elected research fellows at Girton College, 921; title of Stokes lecturer in mathematics conferred on Dr. M. Born, 957
Canada, Three Commercial Sands of, L. H. Cole and R K. Carnochan; S. C. Ells, 953
Canadian: Arctic, Expedition to the, 864, Water Power Developments during 1933, Dr. B. Cunningham, 782
Cancer?: Does the Daily Injection of Small Quantities of Aluminium favour, G Bertrand and P Serbesca, 770, Hospital (Free), award of a scholarship to Mrs Boyland, 136, Mice Susceptible and Resistant to, Chromosome Differences in, Prof C L. Huskins and Miss E Marie Hearne, 615, Mortality in the Australian Commonwealth, Dr. M. J Holmes, 219; Research, 905
Cane-Rats, 524
Cannibalism in North-West America, Dr W C MacLeod, 987
Capraric Acid, G Koller and K Pöpl, 40
Capsian Industry, R. Vaufrey, 107
Carbon: Assimilation by *Chlorella* in Windermere, L. Loose, Dr. W. H. Pearsall and F. M. Willis, 543; Dioxide: Afterglow of, A. G. Gaydon, 984, to Prevent Ignition of Firedamp by Sparks, M. J. Burgess and Prof R. V Wheeler, 109, Monoxide: and Hydrogen, Chemical Action of the Condensed Spark on Mixtures of, H. Lefebvre and M van Overbèke, 586, Ångström Bands of, Predissociation in the Upper Level of the, Prof D Coster and F Brons, 140
Cardiff University College, gift from the Rothschild residuary fund, 805
Carniola, Treasures of, C Hawkes, 164
Carotine in the Organism, S Balachovskij, 699
Carpenter, George W, fund of the Academy of Natural Sciences of Philadelphia, award of the, to Dr F W. Pennell, 457
Carrion-infesting Flies, Parasites of, A C Evans, 500
Casuarinas, Coccidæ of the, W. W Froggatt, 76
Cathode: Anode and, 697, Beam, Diffraction of, by Simultaneous Reflection from Two Different Specimens, N A Shishacow and Mrs L I Tatarinowa, 686
Cathodic Polarisation of Metallic Electrodes by means of the Heyrovsky and Shikata Polarigraph, I Zlotowski, 771
Cats, White, and Deafness, Dr C C Little, 215
Cattle Pleuro-pneumonia, Organism of, Growth Phases of the, Prof J. C. G Ledingham, 296
Caucasus, Archæology of the, Prof R W Fessenden, 919
Causality: a Law of Nature or a Maxim of the Naturalist? Dr L Silberstein (*Review*), 235
Cautchouc in Tau sagiz, Process of Assimilation and Formation of, V Novikov, A Gretchushnikov, J Barmenkov and A. Nosov, 227
Cawthron Institute: Achievements of the, Prof T. H. Easterfield, 71, Research at the, 71
Celestial Mechanics (*Review*), 740
Cell Nucleus, Relation of Materials of the, to the Lethal Action of Ultra-violet Radiation, J R Loofbourow and F F Heyroth, 909

Ghost Moths of Australia, N B Tindale, 465

Gibbs, Willard, medal, award of the, to Prof H C Urey, 284

Gibraltar, Rock of, Air Currents around the, J H. Field and R Wardon, 501

Giorgi (M K S Ω), System of Units, The, 597, Sir Richard Glazebrook, 874

Giza, Early Art at, 444

Glasgow University, Conferment of honorary doctorates, 993

Glass Ancient, Barium in, H C Beck and Prof C G Seligman, 982, Medieval, M Chesneau, 181, Sheet and Plate, Manufacture of, Major R M Weeks, 347

Gleichzeitigkeit, Das Problem der, Dr. K. Vogtherr (*Review*), 631

Gliding Meteorology and, Sir Gilbert Walker, 870, Flight, Meteorology of a, G. E Collins, 688

Glucides, Metabolism of, action of certain alkaloids on the, by *Aspergillus niger*, G. Mezzadroli and A Amati, 391

Glycocol, Action of the Ultra-Violet Rays on, V. Henri, C. Weizmann and Y Hirshberg, 338

Gmelins Handbuch der anorganischen Chemie. Achte Auflage. System-Nummer 35· Aluminium Teil B, Lief. 1. System-Nummer 54: Wolfram (*Review*), 966

Gobi Desert, Riddles of the, Sven Hedin Translated by Elizabeth Sprigge and C Napier (*Review*), 159

God, The Unknown, A Noyes (*Review*), 702

Goethe als Chemiker und Techniker, P. Walden (*Review*), 370

Gold Copper Alloys, Structure of the, W Broniewski and K Wesolowski, 427, in the Water Courses of the Canton of Geneva, Proportion of, J J Pittard, 339

Goldfish, The Cult of the, T C Roughley (*Review*), 435

Golgi Apparatus in Protozoa, Joyce C Hill, 219

Goodyer's Dioscorides (*Review*), 231

Gothes naturwissenschaftliches Denken und Wirken (*Review*), 370

Government and Citizenship in the Modern World, Problems of, Walter Elliot, 130, The Devolution of, 393

Granite of Schärding (Upper Austria), G Horninger, 808

Graph Papers, Wightman Mountain, Ltd, 608

Graphic Statistics, A F Dufton, 37

Graphite, Magnetic Anisotropy of, Prof K S Krishnan, 174

Grassland and Grazing, Martin Jones, 839, and Grazing Research, 643

Gravity Intensity of, in the North-East of China, P Lejay and Lou Jou Yu, 807, Work in East Africa, 989

Gray, Thomas, memorial prizes of the Royal Society of Arts, award of, to Commdr R D Binney and Dr A B Wood, F D Smith and J A McGeachy, 325

Great Western Railway, 389

Greeks, The Scientific Spirit of the, Dr E J Holmyard (*Review*), 357

Green Flash at Sunset, Lord Rayleigh, 846

Greenkeeping Research, Journal of the Board of, No 9, 135

Greenland South-East Coast of, A Supposed Submarine Ridge along the, Dr Å V Tåning, 326; Strange Sounds from Inland Ice, Dr A Dauvillier, 836

Growth and Development, A Study of, Miss R M Fleming, 828

Guinea Pig, Reproductive System in the, T. Nicol, 542

Gutta Percha, Balata and Caoutchouc, Prof G G Henderson (Bedson Lecture), 866

Guy's Hospital Medical School, Dr G P Wright appointed Sir William Dunn professor of Pathology at, 224

Gyroscopic Stabilization of Land Vehicles, The, Dr J F. S Ross (*Review*), 400

Habitation Wastes, Sanitary Disposal and Agricultural Utilization of, by the Indore Process, F K Jackson and Y D Wad, with Notes on the Sanitary Aspect by Lt-Col J. R J Tyrrell and Lt.-Col M A Nicholson, 955

Habits Acquired, Inheritance of, Prof. E W MacBride, 598, S Maulik, 760

Hachette, J-N-P, Death of, 73

Haeckel, Ernst (1834–1914), Prof E W MacBride, 198, Dr W. H Brindley, E W M, 331

Hæmoglobin (4–7), Kinetics of, F J. W. Roughton, 338

Hafnium and other Elements, Constitution of, Dr. F W Aston, 684

Hainan, Expedition to, 561

Hair Direction in Man and Apes, Dr. T D Stewart, 987

Hardness Tests, Brinell and Diamond Pyramid, Minimum Dimensions of Test Samples for, G A Hankins and C W Aldous, 470

Harmonic Functions, Theory of, R Wavre, 339

Hartley Botanical Laboratories [Liverpool], Publications of the, Nos 1, 2, 4, 6, 7 Studies in Advancing Sterility, Parts I to V Prof J McLean Thompson Part 11 The Theory of Scitaminean Flowering. Prof. J McLean Thompson No. 3. The Life History and Cytology of Sphacelaria Bipinnata Hilda B. Clint No 5 The Cytology of Callithamnion Brachiatum W T Matthias No 9 A Contribution to Knowledge of the Mesogloiaceae, etc Mary Parke. Nos 8, 10 Studies of Flowering in Heterostyled and Allied Species, Parts I and II. J. Stirling (*Review*), 704

Harze. Die, Die botanischen und chemischen Grundlagen unserer Kenntnisse über die Bildung, die Entwicklung und die Zusammensetzung der pflanzlichen Exkrete, Prof A Tschirch und E Stock Dritte Auflage von Prof A Tschirch Die Harze und die Harzbehälter. Band 1 (*Review*), 478
Hausmann, Prof J F, of Göttingen, 994
Hawaii: Archæology of, J G. McAllister, 500, Birds of, 289
Hawaiian Cypræaceæ, Dr. F A Schilder, 875
Hawke's Bay Earthquake of February 3, 1931, The, Dr C. Davison, 841
Hawksley, Charles, prize of the Institution of Civil Engineers, award of a, to H G Cousins, 683
Headlamps on Motor Cars with a Yellow Beam, A Blondel, 807
Health, Ministry of, appointment of Dr Jane H Turnbull and Dr J M Hamill under the, 98
Hearing The Helmholtz Resonance Theory of, C S Hallpike and A F Rawdon Smith, 614, E B Wedmore, 983
Heart: Diseases of the, Described for Practitioners and Students, Sir Thomas Lewis (*Review*), 480
Heat, Production of, in Supraconductors by Alternating Currents, H London, 497
Heavy. Hydrogen 881, Transmutation Effects Observed with, Dr M L Oliphant, Dr P Harteck and Lord Rutherford, 413, Water Gilfillan, 537, Biology of, Prof G N Lewis and others, 620, Commercial Production of, 604, in Natural Water, Proportion of, H A C McKay, Sir Robert Robertson, 611, of Low Concentration, Parasitism in, E J Larson and T Cunliffe Barnes, 874, Production of Large Quantities of, Dr L. Tronstad, 872, Reaction of, with Metallic Sodium, Dr J Horiuti and Dr A L Szabo, 327
Hebrew Social Life and Custom, Ancient, as Indicated in Law, Narrative and Metaphor, late Prof R H Kennett (*Review*), 4
Heleochloroplasts, R Savelli, 391
Helium and other Rare Gases, Lord Rutherford, 825, Condensed near Absolute Zero, Behaviour of, Prof F. Simon, 529, Some Thermal Properties of, R Kaischew and Prof F Simon, 460, Electrons in, Small Angle Scattering of, F C Poultney and Prof R Whiddington, 685, from Radioactive Minerals and Rocks, Experiments on Evaluation of, V Chlopin, E Herling and Prof E Joffe, 28, in Beryl, Lord Rayleigh, 69, Liquefaction of, by an Adiabatic Method without Pre-cooling with Liquid Hydrogen, Prof P Kapitza, 708
Helmholtz Resonance Theory of Hearing, The, C S Hallpike and A F Rawdon Smith, 613, E B Wedmore, 983
Helminthosporium avenæ, Morphology and Biology of, R W G Dennis, 617
Helwan Observatory, Dr R Madwar appointed director of, 645
Hemiptera-Heteroptera, Phylogeny of, W E China, 68
Henbury Meteorites, Surface Markings of the, R Bedford, Dr L J. Spencer, 575
Herschel, Sir John, at the Cape, 73
Hessian Fly, Parasites of the, A B Gahan, 728
Heterogeneous Mass in Rotation, Complete Evolution of a, A Véronnet, 75
Heterogony, Rapid Growth-Rate and Diminishing, B Dawes and Prof J S Huxley, 982
Heusler Alloys, Crystal Structure of the, A J. Bradley and J W Rodgers, 390, 877
Hexane and its Isomers, Preparation and Some Physicochemical Properties of, Maman, 847
High -Frequency Measurements, A Hund (*Review*), 364, -Vacuum Leak Device, G A Whipple, 426, -Voltage Testing, B L Goodlet, 491
Himalayan Poppies (*Review*), 777
Hispine Beetles, Larvæ of, Structure of, S Maulik, 107
History and Geography Teaching and Moral Disarmament, 805
Holderness, Forests of, 337
Holley Mott Continuous Counter-Current Washery and Petroleum Products, E Thornton, 69
Holocentrus ascensionis, Osbeck, Colour Changes in the Isolated Scale Iridocytes of Squirrel Fish, D C Smith, 151
Hong-Kong, Land Snakes of, G A C. Herklots, 535
Honours for Men of Science, 621
Hope Farm, Jamaica, History and Management of the, H H Cousins, 264
Hordeum vulgare, Haploids in, D. A Johansen, 960
Hornbeam Bark, Components of, O Brunner and Gertrud Wiedemann, 39
Hornblende in Igneous Rocks, Crystallisation of, W Q Kennedy, 846
Horse (Stallion) Urine, Crystalline Œstrus-producing Hormone from, C Deulofeu and J Ferrari, 835
Horticultural Education Association Year Book, Vol 2, 135
Hot Surfaces, Electrical Condition of, J C Stimson (5), Prof G I Finch and B W Bradford, (6), 302
Hottentot Language, Phonetics of the, D M Beach, 339
Housing Conditions and Respiratory Disease, Dr C M Smith, 828
$HSbO_3$, Fixation of, by Some Aromatic Monoacid-monoalcohols, Duquénois, 75
Human Accidents, Causes and Prevention of, Dr C S Myers (Chadwick Lecture), 409, Biology and Legalised Sterilisation, 155, Embryology and Morphology, Sir Arthur Keith Fifth edition (*Review*), 195, Genetics, the Technique of (*Review*), 307, Personality, The, Dr L Berg (*Review*), 374, Reproduction Prof E W MacBride (*Review*), 359, The Science of, Biological Aspects of Sex, Prof H M Parshley (*Review*), 359
Humus, Conversion of Municipal and Village Wastes into, 954
Hundred Years Ago, A, 1
Hunting by Scent, H M Budgett (*Review*), 548
Hydrated Salts, Artificial Dehydration of, by Means of Solar Energy, A Nikolaev, V Vdovenko and P Pochil, 699
Hydraulics, Prof H W King and Prof C O Wisler Third edition (*Review*), 159
Hydrazine, Oxidation of, by Potassium Ferricyanide, T N Richardson and K C Bailey, 698
Hydrazoic Acid, Franklin, 801
Hydrocarbons Spontaneous Inflammation of, Influence of Pressure on the, M Neumann and V Estrovich, 105, Dr H F Coward, 463 with a High Antidetonating Value, Possible Consequences of the use, in Internal Combustion Engines of, Bonnier and Moynot, 114
Hydrofluoric Acid, Densities of Aqueous Solutions of, L. Domange, 471
Hydrogen Absorption of, by Nickel, J Smittenberg, 872, and Chlorine, Photochemical Union of, Bateman and Allmand, 537, Cyanide, Vibrational Energy Levels of, A Adel and Prof E F Barker, 29, Diplogen from, Chemical Separation of, A Farkas and L Farkas, 139, Fractionation of, by Diffusion through Palladium, V Lombard and C Eichner, 659, Heavier Isotope of, The Reaction between Oxygen and the, C N Hinshelwood, A. T Williamson and J H Wolfenden, 836, Heavy 881, Sir J J. Thomson, 280, and Heavy Water, Prof H C Urey, 197, Designation of, Prof H C Urey, F G Brickwedde and G M Murphy, Prof H E Armstrong, 173, Designation of, Dr H V Sidgwick, 256, Isotope, Electrolytic Concentration of the, B Topley and H Eyring, 292, Isotopes of, Chemical Separation of the, Dr. E D. Hughes, Prof C K Ingold and C L Wilson, 291, Kinetics of Reactions of, H. W. Melville, 947; Transmutation Effects Observed with, Dr. M L. Oliphant, Dr P Harteck and Lord Rutherford, 413, through Steel, Passage of, T N Morris, 217, Iodide, Benzene and, in the Liquid and Solid State, Raman Spectra of, H Epstein and Dr W Steiner.

910; Ionisation of, Enzyme Catalysis of the, Dr. B Cavanagh, Dr J. Horiuti and Prof M Polanyi, 797, Isotopes: of, Zeeman and de Gier, 581; Reaction Rates of the, Prof. M Polanyi, 26, Separation of, by Diffusion through Palladium, L Harris, W. Jost and R W. B Pearse, 507; Stark Effect for the, Prof J S Foster and Dr. A. H. Snell, 568, Replacement, Catalytic, and the Nature of Over-Voltage, Dr. J A V Butler, 26; Dr J Horiuti and Prof M Polanyi, 142, Selenide, Magnetic Rotatory Power of, R. de Mallemann and P. Gabiano, 735, The New, Lord Rutherford, 481; 488; Through Steel, Passage of, Prof. C A Edwards, 379, with Sulphur, Homogeneous Combination of, Influence of Oxygen, Sulphur Dioxide and Moisture on the, E E Aynsley and Dr P. L Robinson, 723, (Hydranes), The Roll-call of the, Prof H E Armstrong, 538
Hydroids as Enemies of Fishes, Dr E W Gudger, 728
Hydro-Oxygen Microscopic Exhibition, 337

Ice: in the Arctic Seas, 952; Periodic Structure in, Dr S. C Blacktin, 613
Ideals of a Student, Sir Josiah Stamp (*Review*), 157
Image-distortion and other Effects Due to the Glass-thickness in Lens Systems, H D. Taylor, 37
Imperial College—Royal College of Science, D Brunt appointed professor of Meteorology, 336

School Certificate Examination, 182
Science Abstracts, Index parts for 1933, 492, and Democracy Adjusting the Laws of Advancing Mechanization to the Objectives of Civilized Policy, F Trinca (*Review*), 477, and God, B Bavink Translated by H S Hatfield (*Review*), 857, and Human Welfare, Prof F S Marvin (*Review*), 310, and Intellectual Liberty, 701, and Philosophy, 341, and Politics, Prof J B S Haldane, Prof A. V Hill, 65, and Railways (*Review*), 46, and the Industrial Depression, H T Tizard, 70, and the Nazis, 941, and the Royal Academy, 709, Application of, to Industrial Processes, H J Cull, 843, attitude of the German Government towards, Prof J Stark, 614, Elementary, in Secondary Schools, F W Turner, 182, International Co-operation in, 961, Masters' Association, Annual Meeting of the, 70, election of Dr N V Sidgwick as president for 1935, 71, Modern, Failure of, to Develop an Adequate Cultural Background to Life, Prof J S Huxley, and others, 58, Museum Handbook of the Collections illustrating Aeronautics 2 Lighter than Air Craft, M J B Davy (*Review*), 891, Handbook of the Collections illustrating Electrical Engineering in the, 683, News a Century Ago, 18, 36, 73, 113, 149, 185, 225, 265, 301, 337, 389, 425, 469, 505, 540, 585, 621, 657, 697, 733, 769, 805, 845, 882, 921, 957, 993, Obligations of, International Status and, Prof J. Stark, Prof A V Hill, 290, Prof A V Hill, 615, on Government Commissions, Representation of, 716, Religion and, A Poet Looks at, Rev J C Hardwick (*Review*), 702, The Heroic Age of, the Conception, Ideals and Methods of Science among the Ancient Greeks, Prof W A Heidel (*Review*), 357, The Outlook of, Modern Materialism, R L Worrall (*Review*), 48
Scientific and Industrial Research, Department of, Report for year 1932–33, 518, and Learned Societies of Great Britain and Ireland, the Official Year-Book of the, Fiftieth Annual Issue (*Review*), 123, and Technical Books, Recent, January 27, iii, February 24, iii, March 31, iii, April 28, iii, May 26, v, June 30, iii, Books, Prices of, 473, Centenaries in 1934, Eng-Capt Edgar C Smith, 13, Discoveries, Rewards for, 661, Discovery The Book of, How Science has Aided Human Welfare, Dr D. M. Turner (*Review*), 310, Method and Politics, 716, Publication and Bibliography, 641, Research may best help in the present world Crisis, How, R W Western, 680, Workers, Association of, Annual Report, 457
Scolt Head Island, J A Steers, 581
Scotland, Chemical Industry in, Report of the Committee on the, 429
Scottish Chemical Industries, 429
Scrapter, a Genus of African Bees, Relationships of, Prof T D A Cockerell and Louise M Ireland, 304
Scurvy in the 17th and 18th Centuries, Dr E. G T. Liddell, 67
Se II, A Perturbation in the Spectrum of, K R Rao and S G. Krishnamurti, 328
Sea -Fish Commission, appointment of a, 19, Research in the, 583

Seeds, Germination of, Sir Arthur W. Hill, 858, 896
Selachii, Teeth of, in Relation to Nutrition, F. Bertolini, 587
Selenium Compound, A, with Thermoelectric Power, M. Levitskaya and V Dlugac, 587
Senefelder, Alois, Death of, 301
Serum Gelatinisation of, by Organic Acids, W Kopaczewski, 808, Phosphatase in the Domestic Fowl, R H Common, 572
Sesamum indicum, L, Classification of, Hildebrant, 764
Sexatilic Acid, G Koller and A Klein, 624
Sex Determination of, Dr C D Darlington, Prof E. W. MacBride, 579; in Haploid Males, possible Cytoplasmic as well as Chromosomal Control of, W E. Castle, 960; Linkage in Mammals, Possibility of Incomplete, Dr C. D Darlington, Prof J B S Haldane and Dr P C Koller, 417
Sexual Regulations and Human Behaviour, Dr J D Unwin (*Review*), 668
Shapley (Dr Harlow), 694
Shark, Basking, in the Bab el Mandeb, Dr H C Delsman, 176
Sheffield · Steel, 49, University A Pool appointed lecturer in Mental Diseases, gift by Dr Foggo, 265, Dr E J Wayne appointed professor of pharmacology, Dr J. Clark lecturer in infectious diseases and H Laithwaite junior research assistant in glass technology, 469, Mrs E Mellanby appointed honorary lecturer in the department of physiology, 769, title of emeritus professor conferred on Prof E Mellanby, 921
Ship's Biscuits, Improved apparatus for making, 425
Short-Circuit Testing Station, 642
Silica Free, in Coal Measure Rocks, Determination of, A Shaw, 846, Fused, Expansion of, L Dunoyer, 770, Silicon and, X-Ray Spectra of the *L*-series of, Prof M Siegbahn and T Magnusson, 257
Silicon and Silica, X-Ray Spectra of the *L*-series of, Prof M Siegbahn and T Magnusson, 257, and Silicides, Preparation of, Electrolysis of Fused Silicates and the, L Andrieux and M Dodero, 586
Silicotextulina diatomitarum, a Siliceous Fossil Foraminifera from the Miocene Diatomites of California, G. Deflandre, 884
Silver Bivalent, New Type of Complex Compounds of, G A Barbieri, 115, Deposits, Electrolytic, X-Ray Examination of, G R Levi and M Tabet, 996, Plating of Mirror Surfaces by Means of Cathode Sputtering, M Romanova, A Rubzov and G Pokrovskij, 698, Thermal Expansion of, by X-Rays, H Saini, 339
Skin, Thermal Radiation of the, Measurement of the, J. Saidman, 38
Sky, Brightness of Various Parts of the, Measurements of the, by Means of a Rectifier Photoelectric Cell, H. H Poole and Dr W R G Atkins, 38
Sloane's, Sir Hans, Collections, 131
Smoke and the Atmosphere Studies from a Factory Town, Dr J R Ashworth (*Review*), 362
Snakes, Sunlight and Death of, H F Blum and C R Spealman, W. Mosauer and E L Lazier, 143
Social and Economic Problems, Data of, 170
Society Islands, Geology of the, H Williams, 220, Rational and Irrational Elements in our, Prof K Mannheim (Hobhouse Memorial Lecture), 410, Towards a Planned, R Brightman (*Review*), 477
Sodium and Phosporus, Induced Radioactivity of, Dr. O. R. Frisch, 721, Chlorate as a Weed-Killer, Dr M. A. H Tincker, 617, Chloride in the Ultra-Violet, Complementary Researches on the Absorption Spectra of, R Trehin, 923, Chloroacetate and Sodium Hydroxide, Velocity of the Reaction between, Prof. H M Dawson and W. Lowson, 807, Formate, Decomposition of, by Bacterium Coli in the Presence of Heavy Water, A. Farkas, L Farkas and J Yudkin, 822
Soil Heating, Practical Methods of, Dr. W F Bewley, 332
Solar: Protuberances, Polarisation of the, B. Lyot, 390; Radiation, Intensity of Ultra-Violet, (λ3200) between April 1925 and June 1933, W. Bernheimer, 427
Solomon Islands, Research in the, 607
Somerville, Mrs, honoured, 505
'Sooty Moulds' of some Australian Plants, Miss E. E Fisher, 31
Sorbose in the Presence of Pyridine, Acetylation of, G Arragon, 923
Sound New Experimental Work in, Prof E N da C. Andrade, 70, Recording, Some Photographic Aspects of, Dr C E K Mees (Sir Henry Trueman Wood Memorial Lecture), 754, Waves, Spherical, Anisotrophy of, Prof S Y Skomtao and L K Su, 214
South African Plants Poisonous to Stock, 972; American Lizards, C E. and May Danheim Burt, 68, Australia, Colonisation of, 993, -Eastern Union of Scientific Societies, arrangements for Congress, 868, Wales Institute of Engineers, award of gold medal to Prof A E Trueman, 136
South's, Sir James, Telescope, 882, 958
Soviet Far North, Plan for Exploring, in 1934, 207
Spearman's General Factor without the Indeterminate Part, Prof H T H Piaggio, 836
Specific Gravity Apparatus, A, C H Cribb, 114
Spectrophotometer, an Ultra-Violet Photoelectric, D. H. Follett, 846
Spectroscopically Pure Substances, Dr R C. Johnson, 880
Spectroscopy and its Applications, Forthcoming Conference on, 562, and Valency (2), C H Douglas-Clark, 543
Spectrum Analysis, Quantitative, Kinematic Method of, A Betim, 507
Spicer-Dufay Colour Film, 678
Spiders, Russian, Prof D Charitonov, 30
Spike Disease, Insect Transmission of, M Sreenivasaya, 382
Spirits, Strength of, Issue of Tables of, 944
Spirochætes dried *in Vacuo*, The Vitality of, Dr E Hindle, 381
Sramanism, Rai Bahadur Ramaprasad Chanda, 680
Stahl, Georg Ernst, Bicentenary of the death of, 714
Stark Effect for the Hydrogen Isotopes, Prof. J S Foster, and Dr A. H Snell, 568
Stars, *A*0 and *F*0, spectrograms of, Relative Widths of the Lines of Hydrogen and of Calcium in the, P Rossier, 884, *A*0 and F0, Total Width of the three Lines H_γ, H_δ and $H_\epsilon + H$ in spectrograms of the, P Rossier, 847, *B*0 and *F*0, Spectrograms of, Width of the Composite Line $H_\epsilon + H$ in the, P. Rossier, 884, Colour Temperatures of, Greaves, Davidson and Martin, 916, Constitution of the, Sir Arthur Eddington (Rickman Godlee Lecture), 284, *F*0, Relation between the Abscissæ of the Extremities of Spectrograms of, P Rossier, 847, *F*0, Spectrographic Photometry of the, P Rossier, 659, Multiplet Intensities in, A D Thackeray, 729, Photoelectric Measurements of, Influence of Colour on the, M Maggini, 587, Shooting, Light of, J Mascart; C Fabry, 507
State. Scientific Services, Co-ordination of, 189, Miss Dorothy Woodman, Editor of NATURE, 610
Statesman's Year Book, The, 1934, Edited by Dr. M Epstein (*Review*), 933

A Hundred Years Ago

ON another page in this issue will be found the names of some of the most notable men of science, engineers and inventors who died in 1834 The list, although it is not an exhaustive one, is representative, and recalls the activities of some of those who lived in the first third of the nineteenth century, a period which was marked by a great increase in scientific studies, in the number of scientific and technical journals and in the list of scientific societies It was, moreover, a period which ushered in those revolutions in transport and communication which will always render the nineteenth century memorable

The year 1834 was perhaps not marked by any such epoch-making event as the inauguration of regular steam navigation by Fulton in 1807, the discovery of electro-magnetism by Oersted in 1819, or the opening of the Liverpool and Manchester Railway in 1830, but the immense activities of the time are reflected in the pages of many publications, in the records of Patent Offices, and in the proceedings of Parliament The world was just beginning to reap the harvest sown in the eighteenth century by such men as Franklin, Cavendish, Black, Lavoisier, Arkwright and Watt, and men's minds were filled with the possibilities of still richer rewards to be gained The achievements of our own days, it must be said, far surpass the visions of 1834, but there are many incidents of that time worth recalling, and during the present year we propose to record some of the happenings—scientific, industrial and social—of 1834 such as would have been noticed in the columns of NATURE had it been founded in that year instead of 1869

A picture of the world of science in 1834 presents many interesting details and includes many notable men In Great Britain, among the outstanding men of science were Brewster, Lyell, Herschel, Dalton, Whewell, Babbage, Faraday, Wheatstone, Forbes, Murchison and Graham, abroad, among the most distinguished were Ampère, Arago, Liebig, Oersted, Hansen, Gauss and Humboldt In 1834, Sir John Herschel, at the Cape, was engaged on his survey of the southern heavens, Faraday at the Royal Institution was investigating the action of the voltaic cell, Wheatstone at King's College was determining the velocity of electricity, Liebig at Giessen was making his laboratory the Mecca for young chemists, while Darwin in the *Beagle* was exploring the coasts of South America

A century ago scientific societies were multiplying apace and the British Association, then three years old, largely through the efforts of J D Forbes, in 1834 held its meeting at Edinburgh Sir Thomas Brisbane was the president a hundred years ago and among the distinguished visitors from abroad was Arago The notable scientific books of the year included Baden Powell's "History of Natural Philosophy", Prout's "Bridgewater Treatise" on chemistry, Arago's "Astronomie Populaire" and the first part of Becquerel's "Traité de l Electricité et du Magnetism". It was also in 1834 that the French railway engineer Clapeyron published in the journal of the École Polytechnique his memoir "Theorie mécanique de la chaleur", which was destined to lead Kelvin to search for a copy of Sadi Carnot's essay of ten years earlier

At the same time, in the world of practical engineering great advances were being made in many directions Improvements were being introduced in the manufacture and working of iron and steel, in the construction of machine tools and in the building of iron structures The Stephensons, Locke, Brunel, Rastrick and others were engaged on the plans for the London and Birmingham Railway and other lines, Hancock, Maceroni, Church and Scott Russell were attacking the problem of applying steam to road vehicles, a promising line of invention the success of which was prevented partly by the railways and partly by legislation, and shipbuilders and marine engineers were planning to build steam vessels capable of crossing the Atlantic under all conditions of weather. Mails and passengers were even then carried to Alexandria by steam, and steam vessels were found in all waters, but a voyage across the Atlantic was still done under sail, occupying sometimes six or eight weeks

The growing interest in all these matters is shown by the records of patents and by the establishment of journals appealing mainly to the engineer and mechanic One of the journals of a century ago which combined in its pages accounts of the work of men of science with descriptions of machines and engineering practice was the *Mechanics' Magazine, Museum Register, Journal and Gazette*, briefly known as the *Mechanics' Magazine*, published first in 1823 In the preface to the first volume its editors said that

> "the object proposed by this publication at its outset was one of entire novelty and no inconsiderable importance A numerous and valuable portion of the community, including all who are manually employed in our different trades and manufactures had begun for the first time, to feel the want of a periodical work, which at a price suited to their humble means, would diffuse among them a better acquaintance with the history and principles of the arts they practise, convey to them earlier information than they had hitherto been able to procure of new discoveries, inventions and improvements and attend generally to their peculiar interests as effected by passing events."

The successful way in which the journal fulfilled these objects led Dr. Birkbeck, at the opening of the London Mechanics Institution—now the Birkbeck College—to declare that the *Mechanics' Magazine* was "the most valuable gift which the hand of science had yet offered to the artizan"

The recognition by the editors of the *Mechanics' Magazine* of the interdependence of abstract science and mechanical progress was but a sign of the times Scientific thought was invading many departments of human endeavour, and the advancement of science was seen to be a matter of national importance. It was this that had led to the founding of the British Association The gibes and sallies with which the birth of the "Parliament of Science" was greeted have long been forgotten, but in recalling the events of that time we shall be reminded of the benefits which have come from the labours of some of its founders and stimulated in our attempts to further the welfare of mankind.

Organising British Farming

The Foundations of Agricultural Economics together with An Economic History of British Agriculture during and after the Great War By Dr J A Venn Second edition Pp xx+600+20 plates (Cambridge At the University Press, 1933) 25s net

AN old French proverb asserts that there are three ways in which a gentleman may lose his money without dishonour on wine, on horses and on agriculture The British farmer, whether gently born or not, has had much experience of the last of these methods, but he is perhaps inadequately consoled by the reflection that he has not lost honour For some five or six years now, large classes of farmers have either failed to make a profit or else have actually lost money, and there are great sections of the country where farmers are heavily in debt to the banks or the merchants, and will have some difficulty in getting out Happily the Government is fully alive to the situation, and the strenuous advocacy of the Minister of Agriculture has enabled schemes for the improvement of agriculture to be developed and pressed forward which ten years ago would have seemed quite impossible

The fundamental trouble is the marketing and distribution of the produce The scientific worker can hold himself blameless so far as the immediate difficulties are concerned, though of course he has actually caused trouble by opening up for cultivation regions which fifty years ago were waste and produced nothing However, it is widely recognised that this question of production would right itself if only the marketing and distribution were more effective

The Government schemes now being put into operation involve much organisation of the industry, both for production and marketing The essential feature is that the organisation is to be done by the industry itself, and not by the State The advantages claimed are that the consumer is assured a supply of fresh food of good quality at reasonable price, and has, moreover, the knowledge that more labour is being used on the land, and therefore more people remain self-supporting and are kept from the various public assistance funds, than on the old methods. The farmer, on the other hand, is assured of a market at a price which has some relation to the minimum wage forced on him by law. It is too early to see how the schemes will work out, but among countrymen there is a general tendency to give them a fair trial.

A new factor in the situation is that townspeople are to-day much more interested in British agriculture than ever before in our time, and they are prepared to give up cherished ideas in order that agriculture may have a chance of success This has put a new responsibility on the shoulders of the farmer and the agricultural expert a high standard of efficiency in agricultural production and distribution must be maintained, and the worker must be given a fair share of whatever prosperity comes to the countryside

Fortunately, at this critical stage in the history of British agriculture, Dr Venn has brought out a second edition of his well-known "Foundations of Agricultural Economics" The first edition appeared ten years ago, but this has been so completely revised and so greatly extended that it has become a new book In the meantime, a considerable amount of new material has become available in the form of various Government and other reports, and moreover Dr Venn has travelled widely and greatly enriched his agricultural experience The result is a book which we can unreservedly recommend as a great success

After a description of the various methods of land tenure, past and present, and of certain of the more serious proposals for expropriation, the author passes to a consideration of the relation between size of holding and farming efficiency Good summary tables are inserted showing the main facts very clearly Cereal production and sheep farming emerge as the special prerogative of the large farmer and pig keeping as that of the small-holder, but the main facts are shown in the following figures —

Size group (acres)	Farm capital per acre (£)	Manual workers per acre (number)	Gross output per acre (£)	Gross output per £100 manual labour (£)
20 50	11 4	5 6	10 1	187
50 100	10 8	4 2	7 4	188
150–300	9 3	2 8	5 9	212
Over 500	8 1	2 4	4 8	215

In this table lies the crux of the whole discussion about small-holdings Are we to aim at higher output per man with low capital charges, small number of workers and low output per acre, or shall we prefer higher output per acre with its accompanying higher capital charges, greater density of settlement but lower output per man? If we decide on fostering the system of lower output for the sake of the greater numbers of people settled on the land, who is to bear the burden of the difference between the £187 as the manual output from the small farm, and the £215 as manual output from the large farm ? At present the capital charges of the small farms are largely borne by the State the cost of this Dr Venn estimates at nearly one million pounds per annum The difference in return as compared with the large farm is borne by the small-holder and his family, and a hard life they often have in comparison with the worker employed on the large farm

So long as these arrangements can be maintained, of course the small-holder is likely to survive, for there are always men who prefer independence to paid employment. Dr Venn shows, however, that the attractiveness of the agricultural wage earner's position is steadily increasing, and never in his long history has he been so well off as to-day labour costs, which fifty years ago amounted to 20 per cent of the farm outgoings, amount to-day to 38 per cent , while expenditure on materials, livestock and implements, formerly more than 50 per cent, now is 36 per cent of the total Rent has fallen from 17 per cent to 13 per cent and rates on farmed land from 1 8 per cent of outgoings to nothing It is shown, too, that farm workers frequently become tenant farmers or occupying owners

Some interesting relationships are brought out between the yields of crops and the conditions of cultivation The yield of cereals in different countries varies inversely with the area grown The yield of potatoes, on the other hand, varies directly with the density of population This generalisation will be new to many agriculturists, but the diagram on p 124 is very convincing Dr Venn can find no evidence that this is a question of size of holdings he attributes it to the greater use of spade husbandry and the better supplies of fertilisers and manures in densely populated countries , but one may ask whether the climatic and other physical conditions that make for dense human populations are not also those that best suit the potato crop ?

Throughout the book there are many stimulating suggestions for the investigator in agricultural economics Why, for example, should there be a marked fall in wheat acreages every ninth year from 1877 onwards—masked only in 1922 but brought out again in 1931 ?

Some interesting chapters follow on the recording of the amount of agricultural production, one of the most difficult problems confronting the agricultural expert It is relatively easy in Great Britain to estimate the quantities of food imported, but exceedingly difficult to know how much is produced here Farmers rarely weigh their produce estimates are by eye. Dr. Venn gives reasons for thinking the official estimates are too low, and the disparity between the recent estimates of pigs available for bacon production in the near future, and the number actually offered by farmers, is still fresh in the public mind by reason of the revision it entailed in the quota permitted to Denmark He prefers the estimates of the *Times*, but agrees that the method proposed (and in point of fact now being investigated) of weighing the produce of certain selected areas is the soundest and will give the best results if it can be put into operation

The book concludes with an interesting account of the changes in British agriculture during the War and afterwards, and it gives a good summary of the measures now proposed for its improvement

E J RUSSELL

Social Life in Old Israel

Ancient Hebrew Social Life and Custom as indicated in Law, Narrative and Metaphor (The Schweich Lectures of the British Academy, 1931) By R H Kennett (Published for the British Academy) Pp vi+114 (London Oxford University Press, 1933) 6*s* net

EVERY period has its special interests and similarly the sciences their special fashions During the last century, interest in the Old Testament was predominantly theological and historical, from the point of view of Christian theology and the history of the Christian religion , we, however, in our times have learnt to look at parts of the Old Testament from a social aspect For us, life has changed and its centre has been transferred to the economic and social sphere Prof Kennett's book is pointing to this direction, and we have good reason to tender our grateful admiration to this eminent scholar and our thanks to Prof Burkitt for having published the manuscript after Prof Kennett's death The author has limited his skilful investigation to the Scriptures, and it is amazing what a brilliant picture he has given us from the somewhat scanty indications scattered over the whole Old Testament In this small study he again shows his supreme intimate knowledge of the Scriptures and his great gift of vivid description

The Hebrew people were a nation of peasants ; agriculture was the basis of the social life. The customs and habits were first and foremost rural; therefore most of the book deals with the life of the countryside. We can almost see the Hebrews in their houses, at their meals and at work. We follow them from birth to death, watch them in their rejoicing and mourning It is obvious that the social classification should find its expression in the way of housing, clothing and food The poorer class houses, for example, were built of unbaked bricks, or unhewn stones cemented with clay, whereas the houses of the rich and wealthy were of hewn stone and not seldom had painted or inlaid walls Parables and metaphors teach us that the poor shared their one-roomed house with the cattle As throughout the Orient, the flat roof played an important rôle and also served sometimes as a foundation for summerhouses for the wealthy people. Houses with upper floors contained separate bedrooms and often accommodation for guests Royal palaces, of course, were distinguished by a richer architecture and ornaments and had store-rooms, even wine-cellars

Wine leads us on to the water supply, perhaps more precious, and certainly most important, for the Orient What we read here of the Hebrews of old will be confirmed by every traveller in the Near East Wells are rare and a privilege of the rich Usually, we find a cistern hewn in the rock. We know that Jerusalem was supplied with water from outside by a subterranean conduit (Siloah Tunnel) which was very important in times of war and siege

We read of beds, tables, pottery, lamps and other household utensils, of how the people cleaned and ground the corn. The nomads lived mostly on milk, the non-nomadic majority on bread baked into loaves both leavened and unleavened Were the corn short the poor man ate "a portion of green herbs"—even roots and wild vegetables served as food Strongly flavoured vegetables were the rule, whereas cucumbers, for example, were considered a luxury. There was also animal food, mainly mutton and goat. Locusts, a frequent plague in Palestine, were a common food Grapes took the first place amongst various kinds of fruit, figs and pomegranates were frequent Banquets were held on special occasions, such as the circumcision of newly-born sons, a wedding, etc., accompanied in early times by sacrifices It is amusing to hear that the portion served to each guest corresponded to the esteem in which he was held and to the honour the host wished to pay him.

With regard to clothing, there was a great variety amongst the rich. Girdles were the most common 'garments', they were of various shapes, from the belt to the apron, and of course were used to gather in the coat. A tunic was generally worn next to the skin, the upper classes wore a long robe as an outer garment The material consisted of wool, flax and linen, spinning and weaving were practised at home. The various colours mentioned indicate that dyeing was known Sandals were worn covering the front part of the foot only. A covered head was a privilege of the nobles and the dignitaries Women used various sorts of cosmetics Prof. Kennett states that the status of women was not equal to that of men, but we may say that Jewish women were much more highly respected than any other Asiatic women, eminent women are known and the female characters of the Old Testament show that the Hebrews knew and appreciated the virtues of a good woman. Usually the Queen Mother had a considerable influence.

Music and dancing were a part of religious ceremonies as well as a natural expression of human joy, and there is no indication of their origin in "nature-worship superstition", as Prof Kennett is inclined to think.

As to the occupations of men, first of all was the warrior, next came the owner of flocks and herds The majority, however, earned a livelihood by agriculture, but their social position was considered as somehow inferior. The plough and yoke were the chief implements. The land was divided into portions, and accumulation in one hand to the disadvantage of others was forbidden by law The social justice of old Israel, never surpassed, is to be seen in the laws concerning the land and its distribution, for example, the command to leave the corner of the field to the poor in harvest time as well as to divide the land anew in every seventh year, the year of fallow coinciding with the release of the slaves Land, vineyards and gardens, cultivated by the peasantry, supplied the necessary food for the population, and workers in wood and metal, mechanics, etc., provided the other necessities of life Luxury trades (goldsmiths, jewellers, perfumers) were also represented in the towns A chapter on the administration of justice and law and the verification of a 'trial by ordeal' amongst an Arab tribe of the present day conclude this interesting book.

This is not the place to discuss and appreciate the scholarly value of this work for biblical research, but it may be recommended to those interested in the life described in the Old Testament.

The Problem of Population

Roman Catholic Methods of Birth Control By Dr Marie Carmichael Stopes Pp xv+235 (London. Peter Davies, Ltd, 1933) 6s net

IN this book Dr Marie Stopes is mainly occupied with her quarrel with the Roman Catholic Church, the authorities of which have actively opposed her campaign on behalf of birth-control. But Dr Stopes succeeds in showing that that Church is not so obscurantist as some of the religious bodies more nearly allied to it. For, as she points out, the Church does sanction certain methods of contraception, and her complaint is that these methods are obsolete, since they are ineffective and physiologically undesirable

It is not our purpose to discuss the relative merits of more modern methods, and in particular of the method which Dr Stopes advocates, though in passing we may remark that a great stride forward was made when it was discovered that one of the most effective contraceptives was ordinary soap and water Rather we would wish to point out that whatever method may ultimately be adopted, some form of control is absolutely necessary unless the three great calamities, war, pestilence and famine, described by Tertullian as the divinely appointed agents in regulating population, are again to recur

The biologist feels doomed to play the rôle of Cassandra. he sees catastrophes approaching but is fated for the most part to prophesy to deaf ears It is gradually becoming clear that populations of mammals, birds, and fish at least, and probably of all other animals as well, undergo periodic enormous increases, followed by devastation by multiplying enemies and disease until they are again reduced to their natural dimensions One of the best-known instances of this is the recurring plagues of lemmings, which, urged on by a wild impulse of migration which always supervenes on overcrowding, emerge from the forests which are their natural home, and devastate the cultivated lands These hordes of rats are harassed on their course by crowds of their natural enemies such as hawks and weasels, and they are decimated by disease The last survivors plunge into the Atlantic and swim towards the west vainly seeking for the lost Atlantis that has drifted away from them More familiar phenomena are, however, due to the same cause A succession of good 'fishing years' is followed by others when the yield is poor It has been shown that 'poor years' do not result from a lesser production of spawn What determines a good or a poor year is the number of eggs which survive In a word, it is not the birth-rate but the survival rate which determines the size of the adult population The survival rate in turn is due to the food in the form of diatoms, etc, available for the young when the yolk-sac is exhausted A lucky year in which plenty of diatoms were available has produced a population of herrings which have supplied the fishermen with abundance for sixteen years! When we recollect that all the efforts of modern philanthropy are directed to increasing the human survival rate, the effect of increasing the herring survival rate gives us serious matter for thought

In the Middle Ages, and until as lately as two hundred years ago, the growth of population in England was kept in check by very similar agencies as those which now control the populations of herrings Then, out of every five children born in London, three died before they were five years old Indeed, the sudden increase in population which began in the latter part of the eighteenth century, and which has usually been attributed to the so-called 'Industrial Revolution', has been shown by Miss Buer to have been largely due to vaccination and better drainage.

England is now the most thickly populated country in the world with 486 people to the square mile, our better classes are restricting their families, but the least skilled go on recklessly breeding, and we frequently read of railway workers with eleven children indignantly demanding houses to contain them, of men on the dole with thirty shillings a week producing nine children Foolish and sentimental optimists point to our Dominions, large red patches on the maps, as homes for this increasing population They forget that more than a half of Canada is an icy tundra, and three-quarters of Australia a burning desert It is true that the backbone of the population of both these countries is made up of the descendants of hardy British emigrants; but these emigrants settled long before the days of doles and social services

In the last resort it would appear that wars are always due to racial pressure. Politicians may be foolish and arrogant, but they dare not risk wars unless supported by the people behind them. A feeling of over-population and being 'hemmed in' has obsessed Germany for a long time: the reviewer heard it forcibly expressed by a German friend in 1892 Since the War the over-population of Germany has been proclaimed by Herr Hitler. Japan is about the size of the British islands, but only about one tenth of its area is arable. The population is 61,000,000, and is increasing by one million a year. It is scarcely necessary to look further for causes of the recent Chino-Japanese war Because catastrophes such as those which occur in the animal kingdom do not take place every twenty or thirty years amongst human populations, the short-sighted ridicule the idea that they ever will occur, but the most superficial study of history proves that the optimists are wrong It seems to us that the most stupendous task that lies before our rulers in England is the regulation of population; to see that no one is permitted to bring into the world children whom he cannot support, and that we should breed from the thrifty and competent and not from the idle and shriftless

Insects and Man

(1) *Medical Entomology* By Prof Robert Matheson. Pp xiii+489 (London. Baillière, Tindall and Cox, 1932) 29*s*

(2) *Medical Entomology. a Survey of Insects and Allied Forms which affect the Health of Man and Animals.* By Dr. William A Riley and Dr Oskar A Johannsen. (McGraw-Hill Publications in the Zoological Sciences) Pp xi+476. (New York McGraw-Hill Book Co, Inc, London· McGraw-Hill Publishing Co, Ltd, 1932) 27*s* net

WHILE medical entomology is mainly concerned with the parts played by insects and ticks in the transmission, causation and spread of disease, its limits have to go farther afield It needs to embrace all kinds of stinging creatures, species with vesicating and urticating properties, and other forms which function solely as intermediary hosts of human parasites. The growing subject of myiasis requires full exposition and, to-day, the utilisation of dipterous larvæ as healing agents in cases of chronic osteomyelitis can scarcely be passed over. A modern textbook will also need to discuss the rôle of Oscinid flies in connexion with conjunctivitis. the little-known diseases of turalæmia and onchocerciasis, together with the growing importance of mites (*Trombicula*, etc), and of sand-flies in relation to obscure tropical and subtropical diseases The literature in these diverse fields grows with such rapidity that *few*, excepting professed medical entomologists, can keep properly abreast of current developments This task is rendered the more difficult owing to the range of periodicals, monographs and government publications that have to be consulted.

(1) Dr Matheson's book is to be commended as a handy and up-to-date manual He has explored his subject with thoroughness and provided a clear and orderly presentation of facts and theories. He has, in fact, written a thoroughly sound and comprehensive introductory text which should appeal to the entomologist, medical man and student alike The bibliographies at the ends of the chapters greatly enhance its value, and its two hundred or so illustrations are clear and well chosen, none of these latter is a familiar 'old stager' The book is singularly free from omissions and misprints, but we think that its utility may be restricted owing to its somewhat high price

(2) Messrs Riley and Johannsen explain in the preface of their book that it is a revision of their earlier manual entitled a "Handbook of Medical Entomology", published in 1915 It differs from its predecessor in that the subject matter has been rearranged while the text has been extended and much new knowledge incorporated In a compass of little more than 450 pages, practically every known disease or affection connected directly or indirectly with insects or other arthropods is taken into account The essential facts respecting the etiology of such diseases are clearly presented while preventive and remedial measures are adequately discussed.

On the entomological side, very full taxonomic keys serve to identify the different species of insects, etc, that are involved, while their habits and measures of control are also dealt with On the other hand, the book is much less informative as regards the structure and physiology of the essential parts and organs directly concerned with disease transmission by insects The reader, for example, will have to go elsewhere for information on the mouth-parts of a mosquito, *Stomoxys* and *Glossina*. Little is said about the complex feeding apparatus of the house-fly and its allies, and a proper understanding of this subject is necessary in order to appreciate the rôle such insects play in relation to disease organisms Apart from omissions of this kind, the book can be recommended as a sound and up-to-date exposition of its subject

The works of a large number of authorities have been drawn upon in its preparation It is, however, disappointing to find many names quoted are omitted from the list of references and that their spelling is not always correct.

Short Reviews

Die Tierwelt der Nord- und Ostsee Begrundet von G Grimpe und E Wagler Herausgegeben von G Grimpe Lief 23 Teil 1.b *Biologische Geschichte der Nord- und Ostsee*, von Sven Ekman, Teil 2 c_2 *Tintinnidæ* (*Nachtrage*), von E Jorgensen und A Kahl, Teil 2 c_3 · *Ciliata libera et ectocommensalia*, von A Kahl, Teil 10 g_3 · *Mysidacea*, von C Zimmer; Teil 10 g_4 *Cumacea*, von C Zimmer. Pp 40+27–146+29–120 (Leipzig Akademische Verlagsgesellschaft m b H, 1933) 24 gold marks

The twenty-third issue of "Die Tierwelt der Nord- und Ostsee" is full of interesting matter Dr Ekman's survey of the biological history is excellent, dealing chiefly with the late and post-Glacial history of the North Sea fauna and of the Baltic fauna and of present-day relicts Dr Zimmer's accounts of the *Mysidacea* and *Cumacea* cover a large number of species with details of their biology, anatomy and systematics, much of the special biology being based on his own investigations

The largest part is occupied by Dr Kahl's monograph on the *Ciliata* (free and ectocommensal) This includes not only those forms which are known from the area, but, because of the probable cosmopolitan distribution of many species, it also embraces those from the seas and brackish waters of the world 700 species are here described with notes on the general characters, biology and habitat Original instructions for collecting and a short paragraph on the culture of these interesting Infusoria are added Out of 117 pages, 100 are taken up with the systematic account, which consists of keys to the orders, sub-orders, families and genera and, under each genus, a list of species with short diagnoses. Full-page figures containing many drawings, as well as text figures, illustrate these To describe so many forms in so small a space is an achievement which must have involved an enormous amount of work, only possible from one who knows his subject very thoroughly In Dr Kahl we have such a specialist and he is to be congratulated on the result, which will be helpful to all workers

Colon Classification By S R Ranganathan Part 1 *Rules of Classification*, Part 2 · *Schedules of Classification*, Part 3 *Index to the Schedules* (Madras Library Association Publication Series, 3) Pp xiv+128+136+106 (Madras Madras Library Association, London · Edward Goldston, Ltd, 1933) 15*s* net

The interesting library classification code set forth in this book by the Librarian of the University of Madras differs from others in that instead of showing a class subdivision for every topic, the schedules contain standard divisions arranged into groups according to function or characteristic, and the class-mark of any topic is obtained from a combination of the appropriate divisions of the various groups arranged in a specified order, the connecting links between the different groups being a set of special devices of which the most important is the colon from which the system derives its name It is rightly claimed that the schedule thus produced, while securing as great a degree of minuteness for the classification, occupies a great deal less space in print, but it has the disadvantage that the class allotment of every book necessitates reference to several sections before its correct place is found.

The classification, though dictated to a certain extent by the needs of the system, has been well done, and the scheme is both elastic and comprehensive, while at the same time providing for sensible variations to meet local circumstances The schedule for Indian literature has been very fully worked out The class-mark for NATURE under the scheme would be Am 561 M 68, and that for the book itself regarded as the classification code of the University of Madras Library, 251 33 · 44111q N33 A G

A Textbook of Biochemistry · for Students of Medicine and Science By Prof A T. Cameron. (Churchill's Empire Series) Fourth edition Pp. xi+556+2 plates (London. J. and A Churchill, 1933) 15*s*

This is the fourth edition of a work which is based on lectures given to students of medicine It is divided into six sections of which the first is introductory and physical, dealing with the conceptions of catalysis and hydrogen ion concentration Section 2 describes the constituents of the food-stuffs, sugars, fats, proteins, etc Section 3 treats with the chemistry of digestion, the circulation and the excreta, Section 4 with all that is comprised under the heading "Intermediate Metabolism". Section 5 handles quantitative metabolism, and the final section introduces the student to immunology and pharmacology To do all this within the compass of 500 pages is a feat; at the same time one cannot help reflecting how much the medical student is expected to master, especially when some of the complex formulæ are examined In this edition such subjects as the endocrine principles, the vitamins and the sterols have received increased attention as the knowledge of them has progressed The author has wisely incorporated recent work even at the risk of seeing some of it retracted; in this connexion he might well have made reference to that of Hilditch on the constitution of the fats.

As a minor correction we might note that strophanthin is no longer regarded as containing rhamnose and mannose, but consists of glucose and a unique sugar, cymarose. The book merits continued success.

Plant Distribution in the Aberystwyth District: including Plynlimon and Cader Idris. By Prof. Lily Newton. Pp. 50+8 plates. (Aberystwyth: The *Cambrian News*, n.d.) n.p.

THE scope of this book is to give a readable ecological account of a district which, as Prof. Salter rightly remarks in his preface, has been much neglected by botanists. Accounts of the physical features and geology of the district, and a brief section devoted to the ecological study of plant distribution, precede descriptions of the various types of maritime, lowland and upland vegetation of the area bounded by Aberayron and Tregaron on the south and Plynlimon and the Barmouth estuary and Cader Idris on the east and north. Descriptions of the submerged forests of Cardigan Bay and of the old lead-mining areas and their ecological significance are included and a comparison given of the two mountains, of which Cader Idris is the more varied and floristically richer.

Quantitative data as to plant frequencies and soil and light conditions are excluded from the treatment of the plant associations, and both English and Latin names are given for the species cited. Too brief a section dealing with factors influencing distribution emphasises the relation between altitude and plant distribution, but scarcely does justice to the rôle of soil factors. The book should be useful as a general ecological survey of the district and as a basis for more detailed investigation of its constituent plant associations.

The Cultivated Conifers in North America: comprising the Pine Family and the Taxads: Successor to The Cultivated Evergreens. By L. H. Bailey. Pp. ix+404+48 plates. (New York: The Macmillan Co., 1933.) 37s. 6d. net.

ALTHOUGH this book deals very largely with the conifers that can be grown out of doors in North America, the information it contains will be found to be useful to people in other countries also. Moreover, the range of conditions existing in North America is such that the majority of conifers from other regions thrive in one or another part of the continent; therefore comparatively few kinds are omitted.

The work is divided into two parts; the first is devoted to systematic descriptions of the genera and species hardy in North America, and the second to the cultivation of conifers for decorative purposes. A very useful feature of the first part will be found in the very good keys to species that accompany the descriptions of the larger genera. The second part of the book deals with cultivation, propagation, the selection of kinds for different positions, pests and diseases. Amongst name alterations, the name of the Douglas fir has been changed back to *Pseudotsuga Douglasii* from *P. taxifolia* without explanation. If such a change were necessary, a reason should have been given. Presumably *P. taxifolia* is regarded as a homonym.

Elementary Statistical Methods. By Dr. E. C. Rhodes. (London School of Economics and Political Science: Studies in Statistics and Scientific Method, No. 1.) Pp. v+243. (London: George Routledge and Sons, Ltd., 1933.) 7s. 6d. net.

IF this first volume of a new series of studies gives a true indication, the series is designed to introduce statistics to a public for which no language can be too elementary, no remark too obvious, no emphasis too crude. The attempt is significant, for stability of democratic government may well depend on the possibility of such an introduction, and when the experiment is made in the popular press, the journalist will be fortunate in having an authoritative model. Dr. Rhodes describes excellently the precautions with which the raw material of a statistical inquiry should be compiled, the nature of simple and weighted averages, the meanings of median and quartile and of deviation and dispersion, the use of graphs, and the analysis of time series by means of a moving average. There is a wealth of numerical and graphical illustration, but the index does not conform to any reasonable standard. E. H. N.

Broadcasting. By Hilda Matheson. (The Home University Library of Modern Knowledge, No. 168.) Pp. 256. (London: Thornton Butterworth, Ltd., 1933.) 2s. 6d. net.

THIS book is written by an author fully conversant with the subject. That radio communication is not unmixed good is generally admitted, and that its possibilities have as yet only partially materialised is patent to all who have watched its development. Anything that tends to bring about *rapprochement* between the nations is welcome. The suggestion offered, that radio in the home may increase the sum of laziness, must be noted, but this may be more than balanced by the broadening outlook of rural communities. Finally, it may be quoted, that "Broadcasting will only mechanise men, if it becomes the tool of a mechanistic State". P. L. M.

100,000 Whys: a Trip around the Room. By M. Ilin. Translated by Beatrice Kinkead. Pp. 138. (London: George Routledge and Sons, Ltd., 1933.) 3s. 6d. net.

THOSE best know how little they know, who are credited with knowing everything; and it may be that M. Ilin's small guide to general knowledge will serve in lessening to a slight degree the load of ignorance which so many carry. "Knowledge comes, but Wisdom lingers", so that even when our learning is the greater, by reason of the assimilated contents of this book, our wisdom may be not one whit increased. Both text and illustrations are likely to appeal most to the immature section of the general public to whom M. Ilin offers his book. The translation merits full praise.

Planetary Photography*

By DR. V. M. SLIPHER

THE Lowell Observatory was founded in 1894, by the late Percival Lowell, who maintained and directed it during his lifetime and endowed it by his will, that it might permanently continue astronomical research and in particular that of the planets. For nearly four decades now, it has been occupied with planetary investigations. It is situated at Flagstaff, Arizona, because, of the numerous places he had tested, it was here that Lowell found the conditions best for planetary studies. The major instruments of the Observatory are: (1) 24-inch aperture Clark refractor of 32 feet focus, (2) 42-inch Clark reflecting telescope, (3) a new 13-inch photographic telescope, (4) 15-inch Petitdidier reflector, and in addition several smaller instruments, together with a number of spectrographs, special cameras for photographing the planets, radiometric apparatus for use with the 42-inch reflector, for measuring the heat of the planets, and such laboratory equipment as is needed in the work carried on.

FIG. 1.—Photographs of Mars showing the shrinking of the polar cap and the growth of dark areas.

During the first decade, the work at the Observatory was mainly visual observations of the planets, then it was extended to include their spectrographic study, and during the second decade direct photography of the planets was added and has been continued since, giving a permanent record of them to the present time. During the past decade, their heat measurement has also been made a regular part of the observational programme. In short, whenever it has been possible to apply new means, they have been made use of in order that the planets be studied from every possible point of view.

During the early years of the Observatory, Lowell was able to observe Mercury and to confirm Schiaparelli's conclusion that the planet constantly keeps its same face to the sun, as our moon does to the earth. Thus its small mass and the intense heating by the sun long since dissipated its atmosphere. Venus proved more difficult, and with very faint surface markings, its length of day was left somewhat uncertain, while from all considerations it appeared that this planet also keeps the same face constantly toward the sun, for even the spectrograph showed no evidence of a day shorter than a few weeks. Spectral studies of Venus have failed to give any evidence of an earth-like atmosphere, no bands of oxygen or water being found, although it might have been expected that Venus would be the planet most like the earth.

From this non-committal and veiled planet we pass to the best observed of all, Mars, which has long attracted wide interest. Martian seasonal change shows itself clearly in the polar caps, which alternately increase and decrease, and in the blue-green markings which darken in the growing season and pale again as winter approaches, the great ochreish expanses, changing little from winter to summer, except as influenced by light spots and clouds. The shrinking of the polar cap with summer's coming is to be seen in Fig. 1, where are shown five photographs of the same face of the planet showing particularly the upper hemisphere, but made at Martian seasonal dates. With the contraction of the cap the shaded areas darken and enlarge, as may readily be seen in the photographs.

Dark rifts appear in the melting caps, always at precisely the same time and the same places each Martian year, which clearly prove the caps to be deposits on the planet's surface. Irregularities of the surface must cause this patchy melting of the caps to be repeated always with most punctual harmony to the Martian calendar. Such features of the melting caps are to be seen in Fig. 1. The melting cap is bordered by a dark collar, and is more disposed to be regular in outline than the forming cap, which is irregular in outline and indefinite, and to begin with is erratic storm clouds only. An autumn cap appears at the opposite side of the planet to the polar cap

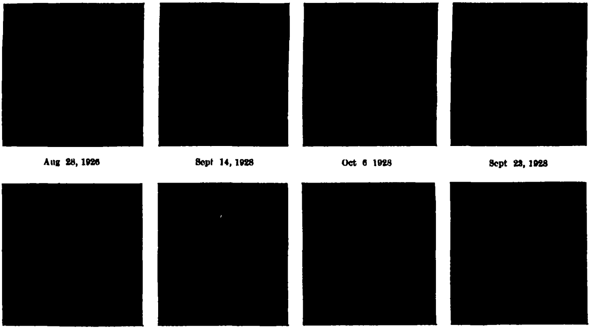
---

* From a discourse entitled "Planet Studies at the Lowell Observatory", delivered at the Royal Institution on Friday, May 19.

The behaviour of the caps means that Mars has an atmosphere, for that is the only vehicle which does such transportation of substance Occasionally, when Mars is so placed that we look a little into its night sky, we see on it a bright streak of light due to a cloud high in its atmosphere, catching the sunlight, while the surface is dark beneath it Such allow us to measure their height above the Martian surface, and a fine one in 1903 was fully 15 miles high, whereas clouds are rarely more than 5 miles above the earth Hence Mars must have quite a considerable atmosphere, and the spectrograph at Flagstaff showed it to contain water and oxygen, but no strange substances. Thus it closely resembles that of the earth, but is less dense, because the Martian surface gravity is only three-eighths of ours There is, therefore, good proof that the polar caps of Mars are snow. Long ago someone suggested they might be frozen carbonic acid gas, but Faraday himself showed experimentally the conditions of pressure and temperature required to solidify this gas; conditions which we are sure cannot prevail on Mars

Lowell, some years ago, deduced the temperature of Mars from a full evaluation of the factors involved, such as albedo, the behaviour of the caps, etc, and arrived at a value of 48° F. This has recently been confirmed by the radiometric measurements made at Lowell Observatory by Coblentz and Lampland.

While there is room for difference of opinion as to the interpretation of the canals of Mars, their existence as true markings on the planet has been clearly established, for they have been photographed and have been seen by nearly all skilled observers who have observed the planet carefully with powerful instruments The Lick astronomers Schaeberle, Campbell and Hussey of the early observers, and Trumpler more recently, all drew the canals Because changes take place in the planet's features in quite short time intervals sometimes, observers may seem to disagree and yet both be right.



Aug 28, 1926 Sept 14, 1928 Oct 6 1928 Sept 23, 1928

Sept 22, 1928 Nov 30, 1928 Oct 6, 1928 Oct 7, 1928

FIG 2 Photographs of Jupiter

Lowell regarded the canals as strips of vegetation along artificially produced water courses, for they, like the larger blue-green areas, darken when the time comes for seasonal growth in vegetation, and this led to the belief that vegetable life, and hence also probably animal life of some degree of intelligence, exist on Mars

Jupiter has received much study at the Lowell Observatory What we see on Jupiter are mostly atmospheric features, apparently nothing of a solid surface appearing Usually so much detail is present that the visual observer, owing to the planet's rapid rotation, has difficulty in recording properly in drawings and notes all he is able to see under good observing conditions. In these circumstances the aid of photography has been very important, and a photographic record of the planet, as complete as possible, has been kept at Flagstaff since 1905. Fig. 2 indicates the nature of the Jupiter markings and gives some idea of their rapid and sometimes extensive changes, which give some hint of the very great activity present on the planet

Spectrum analysis of the light of Jupiter has revealed a great number of dark bands in the red and infra-red, due to the selective absorption of its atmosphere Most of these are yet unidentified, but ammonia is present, and possibly also methane gas. The most remarkable quality of the planet's atmosphere is its rapidly increasing absorption into the longest wave-lengths, which must affect the radiation in a decided manner

April 22, 1921 May 15, 1922

Sept 2, 1929

FIG 3 Photographs of Saturn

Saturn has been regularly observed at Flagstaff, visually, photographically, and spectrographically Lowell studied theoretically the planet's law of mass distribution, the polar flattening and relation of satellites to divisions in the ring system, leading to new results Photographs of the planet and rings in light of different colours show some surprising changes, sometimes from year to year. It was found in 1921, when the earth and sun were very near the plane of Saturn's rings, that, contrary to previous belief, the rings could always be seen, and that the rings caused two dark lines across Saturn's ball, one the shadow of the rings and the other the rings themselves as seen dark against Saturn (Fig 3).

Spectrum analysis of Saturn's light shows much the same absorption bands as were found for Jupiter (except that those of ammonia are weaker in Saturn), so their atmospheres are much alike The rings show no atmosphere, but are meteoric The fact that the cloud belts of Saturn are so much weaker than those of Jupiter is doubtless due to the former having a very great seasonal disturbance owing to its highly tipped axis This factor is practically absent from Jupiter, and so allows its clouds to form and continue strongly belted parallel to the equator, whereas for Saturn the seasonal disturbance tends to destroy such belts

While Uranus and Neptune are each more than sixty times the volume of the earth, their great distances, nineteen and thirty times our distance from the sun, give them only tiny discs even in the largest telescopes, and markings on them are very difficult of observation Hence to get the rotation of Uranus the spectrograph was employed, it showed the planet's day to be 10 7 hours, and the rotation to be in the direction in which the satellites revolve

The spectrum analysis of these two planets has also taught us much as to their atmospheres They bear resemblance to those of Jupiter and Saturn, but show much more intense and numerous absorption bands, the strongest of which are present in the two latter planets This atmospheric band system is much more intense in Neptune than in Uranus, in short, the bands increase from Jupiter to Uranus and again from the latter to Neptune, somewhat with the distance of the planet from the sun

Fig 4 shows the spectra of these four planets compared with that of the moon, and gives a good idea of the manner in which the absorption bands increase from Jupiter to Neptune It is of interest to note that the ammonia band clearly evident in Jupiter, a little way to the left of C, is weak in Saturn, Uranus and also in Neptune

This study of the planets at the Lowell Observatory, in addition to many results not given here relative to the several planets, has much emphasised the differences of the two main groups of planets · Earth, Venus, Mercury and Mars, and the giant group—Jupiter, Saturn, Uranus and Neptune The first group are comparable with the earth in size, in density, in energy they receive from the sun and in atmospheres, so far as they show any at all The other group are much larger bodies, but of much lower densities, and have a very different type of atmosphere, while the solar energy they receive is much less than the earth's share—ranging from 1/26 for Jupiter to 1/900 for Neptune. But these studies indicate that these planets may be much more effectively utilising this small energy gift from the sun than does the nearer group of planets, for their atmospheres, as their spectra show, are as blankets retaining energy of the longer heat-waves, and may let little or none pass out in the heat spectrum available to observers on the earth.

These studies further direct attention to that important break between the two groups of planets between Mars and Jupiter, and emphasise the need of its further study, and perhaps from theoretical grounds as well, for when we know what has happened to produce the asteroids and cause this vast change in the planetary bodies, we shall better understand the past of the solar system.

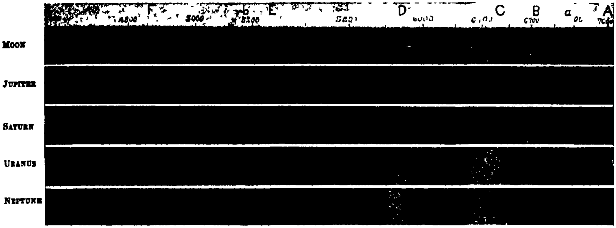

FIG. 4. Spectra of planets and the moon.

Scientific Centenaries in 1934

By Eng.-Capt. Edgar C. Smith, O.B.E., R.N.

THE records of the past year contain accounts of many commemorations of the centenaries of notable men such as Wren, Pepys, Priestley and Trevithick. In some instances the celebrations included the arrangement of interesting exhibitions, the delivery of lectures and the erection of memorials, but in every case they reminded the world of its benefactors and brought to light new information regarding the lives and work of those commemorated. If the sole value of the practice of commemorating centenaries were that it reminded us of great achievements it would be justified, for most men are like Emerson who said: "I cannot even hear of personal vigour of any kind, great power of performance, without fresh resolution." Then, too, we are all debtors of the dead, appropriating from their labours what is pure grain, rejecting what has proved to be chaff and utilising their discoveries and inventions for furthering our immediate ends.

In looking forward once again, it will be found that the centenaries falling within 1934 recall names worthy in every way to be placed beside those brought to mind during the past year. In their own time, and in their particular spheres of activity, few men held higher positions among their fellows than Mendeléeff, Langley, Weismann, and Haeckel, who were all born a century ago, or Jacquard and Telford, who died in 1834. But they only built on the work of their predecessors, and in commencing a short review of the scientific centenaries of 1934, it is of interest to go back to the revival of learning and the days of the Reformation. The outstanding figure in the science of those days was Copernicus (1473–1543), one of whose contemporaries was Otto Brunfels, who died on November 23, 1534, four centuries ago. The son of a German cooper, Brunfels was in turn a Carthusian monk, a Lutheran preacher, a schoolmaster at Strasbourg and a doctor in Berne. His study of herbs caused him to be called a revivor of botany and his name was afterwards given to a genus of plants by Plumier. The year of Brunfels's death saw the birth of another German botanist, Joachim Camerarius (1534–98), son of the learned scholar who reformed the University of Leipzig. The pupil of Melancthon, Camerarius received the degree of M.D. at Bologna in 1562, then settled in Nuremberg and there formed one of the earliest botanical gardens. A French botanist of a hundred years later was Denis Dodart (1634–1707), physician to Louis XIV, a member of the Paris Academy of Sciences and one of the compilers of the "Mémoires pour servir à l'histoire des plantes" published in 1676.

It was but natural that the early botanists should be recruited from the ranks of the physicians, from which came also some of the early chemists Among the medical men of the seventeenth and eighteenth century whose names are indelibly inscribed on the roll of scientific worthies is Georg Ernst Stahl, the bicentenary of whose death occurs on May 14 In 1693, at the age of thirty-three years, he was appointed professor of medicine, anatomy and chemistry in the newly established University of Halle and in 1698 he enunciated the famous phlogiston theory which, embraced in Germany, spread to Sweden, France and England and continued an orthodox article of faith until overthrown by the experiments of Lavoisier In 1716 Stahl removed to Berlin as physician to the King of Prussia, Frederick William I (1688-1740), and there he died Two less famous men who died in 1734 were the French mathematicians Thomas Fantet de Lagny (1660–1734), a foreign member of the Royal Society and for many years royal hydrographer at Rochefort, and Peter Polinière (1671–1734), who it is stated was the first person appointed to deliver lectures on experimental philosophy in the University of Paris

The year 1734 also saw the birth of many individuals who achieved distinction in science and engineering These included Edward Waring (1734-98), F R S , for thirty-eight years Lucasian professor of mathematics at Cambridge, whose "profound researches were not," it was said, "adapted to any form of communication by lectures" , Wolfgang, Baron de Kempelen (1734–1804), the Hungarian statesman and mechanician, who devised an automatic chess player, which was exhibited in London, and a process of printing books for the blind in embossed type , the French agriculturist Francis Rozier (1734–1793), who in 1771 founded the *Journal de Physique et d'Histoire Naturelle* , Thomas Henry (1734–1816), F R S , the chemist, who was first secretary, and later on president of the Manchester Literary and Philosophical Society, and Robert Mylne (1734–1811) the engineer and architect who is buried in St Paul's Cathedral close to Wren Mylne designed the Gloucester and Berkeley Canal, the Eau Brink Cut at Lynn and the first Blackfriars Bridge, the third bridge to span the Thames at London. For a very long period Mylne was the surveyor of St Paul's

Turning to the deaths and births of just a hundred years ago, the list, without being exhaustive, contains many familiar names In 1834 died Jean Nicholas Peter Hachette (1769–1834), a professor at the École Polytechnique, whose development of the descriptive geometry of his colleague, Monge, proved of great value to the constructors of machinery in France , the German astronomer Karl Ludwig Harding (1775–1834), who in 1804 discovered Juno, the third asteroid, and the Swiss physicist Charles Gaspard de la Rive (1770–1834), who like his son Auguste de la Rive was a friend of Faraday On February 26, 1834, Alois Senefelder (1771–1834), the inventor of lithography, died in Munich ; on August 7 Joseph Marie Jacquard (1752–1834), the inventor of the loom for figure weaving, died near Lyons ; on August 19 General Henri Joseph Paixhans (1783–1834), a pioneer in the improvement of artillery, passed away at Metz, and on September 2, Thomas Telford (1757–1834), the great civil engineer, died in Westminster Telford's roads, canals, bridges and docks are to be found in many parts of Great Britain After the death of Rennie he was the recognised head of the engineering profession, and in 1820 he was elected the first president of the Institution of Civil Engineers, a position he held until his death He was buried in the nave of Westminster Abbey and a statue of him is to be seen there in St Andrew's Chapel

So far, all those mentioned have belonged to the western nations of Europe, but of men of science born in 1834 the list may well begin with the names of Langley, Young and Powell, of the United States Samuel Pierpont Langley (1834–1906) will always be remembered for his important theoretical and practical investigations on aeronautics, but he was also distinguished as a physicist and astronomer, and for many years was secretary of the Smithsonian Institution His contemporary, Charles Augustus Young (1834–1908), of Princeton University, was also an eminent astronomer, while Major John Wesley Powell (1834–1902) was, from 1879 until 1902, Director of the United States Bureau of Ethnology and from 1881 until 1894 Director of the United States Geological Survey

These three eminent men were born in the eastern States of America , the birth of the great Russian chemist, Dmitri Ivanowitsch Mendeléeff (1834–1907), carries us to the plains of Siberia, to Tobolsk, where his father was a schoolmaster. Mendeléeff was born on January 27 (O S) or February 8 (N S) and died in 1907 on January 20 (O S) or February 2 (N S) His life and work were the subject of a memorial lecture delivered to the Chemical Society in 1909 by Sir William Tilden Two of Mendeléeff's contemporaries, born in Germany and famous as chemists, were Carl Schorlemmer (1834–92) and Hermann Johann Philipp Sprengel (1834–1906) both of whom, however, spent the greater part of their lives in England, Schorlemmer being the colleague of Roscoe at Owens College, Manchester Sprengel was famous for his invention of the improved mercury air pump and for his work on explosives. Another German man of science born in 1834 was Philipp Reis (1834–74) a pioneer of the telephone whose apparatus was used so early as 1865 by D E Hughes when lecturing before the Emperor of Russia, Alexander II

Leaving the ranks of the workers in physical science for those of the inventors and engineers, mention may be made of Daimler, Wedding, Preece, Woodbury, Vavasseur and Perkins, who were all born in 1834. Loftus Perkins (1834–91), the grandson of Jacob Perkins, was a pioneer in the use of high-pressure steam at sea, and in 1880 built the yacht *Anthracite*, which crossed the Atlantic using steam at 350 lb per sq in ; Joseph Vavasseur (1834–1908) is remembered for his improved method of controlling the recoil of large guns, while Walter Bentley Woodbury (1834–85) was the inventor of Woodburytype and other developments in photography Sir William Preece (1834–1913) was widely known as a distinguished electrical engineer, Gustav Hermann Wedding (1834–1908) was both an honorary member and Bessemer medallist of the Iron and Steel Institute ; while Gottlieb Daimler (1834–1900) will always be remembered as the colleague of Langen, Otto and Maybach, and as the first to construct a high-speed internal combustion engine suitable for road vehicles

In conclusion, passing reference may be made to the approaching centenaries of the birth of Sir John Lubbock, first Lord Avebury (1834–1913) which falls on April 30, 1834, whose writings on primitive man and on bees and ants delighted a large circle of readers, of August Weismann (1834–1914) the German biologist, born on January 17, 1834, who was the first to think out a coherent theory of heredity, and of Ernst Heinrich Haeckel (1834–1919), born on February 16, 1834, who has been spoken of as "probably the most influential advocate of Darwinism"

Experiments in the Stratosphere

IT has recently been reported in the daily Press that an attempt is shortly to be made by balloon ascent to reach higher altitudes than 61,000 ft (pressure 50 mm) claimed to have been reached by Prokofiev and his companions in the U S S R balloon It is to be recalled that observations were made by Regener in 1932 using self-registering apparatus attached to rubber balloons up to a pressure of 22 mm It was reported that the American balloonists Settle and Fordney reached a pressure last autumn of about 64 mm, whilst the minimum pressure from the records of the Belgian flights of Cosyns, Kipfer and Piccard was 73 mm

The new attempt represents a departure from the previous methods in that the observers are to travel in an open basket but will themselves be completely sealed in flexible rubber suits To prevent these from ballooning at low external pressure the suits, adequately supported, will be exhausted down to the minimum that a man can withstand with comfort if he be supplied with sufficient oxygen The advantages claimed are that the great saving in weight by the absence of the heavy gondola of the previous flights will enable the observers to reach greater heights The apparatus has already been tested with safety up to an external pressure supposed to correspond to a height of 90,000 ft —roughly that attained by Regener's balloons These preparatory ground experiments are being conducted by an American, Mr M E Ridge, with the advice of Dr J S Haldane, at the works of Messrs Siebe, Gorman and Co Ltd at Lambeth, London It is assumed that the ballooning of the suit at the greatest height attainable will not incommode the occupant even though he himself is under a very much reduced pressure The observer will be enabled to move about freely and make meteorological and other observations with instruments in contact with the atmosphere

It is true that from the point of view of record breaking, this saving in weight is an important feature, for it was made clear by Dr. M Cosyns, when lecturing in England a short time ago, that the only practical limits imposed turned on the very awkward elongated cigar shape of an extremely large envelope when filled with hydrogen only to a small fraction—one fifth or one tenth—of its capacity on the ground The whole risk lies with the possible entangling of the practically parallel ropes supporting the gondola When once off the ground the mishap cannot be rectified So great was the risk that, in the last Belgian ascent, the balloon was purposely filled with twice as much hydrogen as was required in order to keep the ropes apart, the surplus being discharged en route

Turning now to the instrumental observations, it must be remarked at the outset that the values of *J*, the rate of production of ions per cubic centimetre by the cosmic rays, obtained by the Belgian observers, lie within the limits of those of Regener and agree well with them Those of the stratostat *USSR* are said to agree slightly better with the Belgian than with Regener's results Other interesting experimental results from the Russian source are that the composition of the air is the same at the lowest pressure reached as on the ground, the relative humidity fell from 92 per cent on the ground to 42 per cent on the borders of the stratosphere and that, contrary to expectations, gradients of temperature over a few degrees were experienced within the stratosphere It is noticeable, however, that previous observers have attempted rather too much on each flight, but commenting on the new departure and its relation to previous methods, the barothermograph looks after itself, as does the recording electrometer for obtaining the potential gradient. Perhaps a small advantage would be obtained here in manipulating the leads strung out from the car. The Kolhorster ionisation chamber failed to work on the Belgian flight due to the deposition of body moisture on the insulations, but the advantages of exposing the battery, insulators, electrometers, etc, to the rigorous conditions of the stratosphere are doubtful. Spectrometers for recording the sun and sky light, pyrheliometer for determining the solar constant, air samplers and camera can all be worked in the open. Eyes and ears must unfortunately always be enclosed. The deep purple of the sky noticed by both the Belgian and the Russian observers must always be seen through glass

Of all the observations likely to be made, the greatest promise comes from the projected Wilson chamber experiments by Dr. Cosyns that were mentioned in NATURE of November 25, p 812 The need for a further examination of cosmic rays is urgent, for their origin remains unknown The interesting effect accentuated in the Belgian flights was the difference in the behaviour of the ionisation chamber and the Geiger counter as standardised on the ground with γ-rays from radium and used in the upper atmosphere The relative indications of the counter increase at a greater rate than those of the ionisation chamber, and in the highest altitudes reached, the activity of one has become thrice that of the other The greater attenuation of the ions along the track of the cosmic ray than along that of the standardising β-ray accounts for the comparative falling off of the indications of the ionisation chamber, whilst the counter goes on no matter how small the disturbance This result, however, is deceptive, for as the ground experiments of Blackett and Occhialini have abundantly shown, only a very inadequate part of the life-history of a cosmic ray may be obtained from the study of a localised portion of the track of one of the secondary particles The intrinsic ionisation per centimetre along the track with its secondaries and tertiaries may be just as high as along that of a β-ray It is well known that, of all the instruments, the Wilson chamber set for photographing β-rays and cosmic rays is most delicately poised. Small variations in temperature conditions and expansion ratio with water or alcohol vapour as indicator upset the observations Such an instrument, if it is ever constructed for the purpose, must be used in a closed gondola, on account of its heavy coils for obtaining the requisite magnetic field and extra large chamber for taking in as much as possible of these simultaneous happenings, the non-ionising links, the tracks radiating forwards from diffuse centres consisting of neutral particles and positive and negative electrons and the localised heavy bursts of ionisation supposed to be associated with the complete destruction of a chance heavy molecule

Apart from the investigations in pure science for which such heroic efforts have recently been made and are likely to be made in the future, the reported change in tactics has reopened the question of the feasibility of employing such a flying suit in an open aeroplane flying the stratosphere It is claimed that the control will be easier than from a completely sealed cockpit.

Obituary

MR H R A MALLOCK, F R S

WHEN Mr. Henry Reginald Arnulph Mallock died on June 26, 1933, we endeavoured to find particulars of his career upon which a suitable obituary notice could be based, but were unsuccessful He was an esteemed contributor to our correspondence columns, yet, on account of his dislike for publicity, few personal details were known concerning him, and no one felt able, therefore, to deal adequately with his life and work Dr C V Boys has, however, since contributed to the *Proceedings of the Royal Society* an appreciative account of Mallock's upbringing and some of the products of his fertile brain and mechanical ingenuity We give below an abridgement of this obituary notice and are glad thus to be able to place on record a tribute to a great physicist and engineer

Arnulph Mallock, the youngest son of the Rev. William Mallock, was born at Cheriton Bishop, on March 12, 1851 After leaving school he entered St Edmund's Hall, Oxford, and when he left Oxford he assisted his uncle, Mr W Froude, of Chelston Cross, Torquay, in working out the very beautiful gear of the original ship model tank. In 1876 Mallock went as assistant to the late Lord Rayleigh. He had some doubt whether his mechanical skill would be sufficient to enable him to meet Lord Rayleigh's requirements It would seem that his misgivings were unnecessary for two reasons. He was in fact an accomplished mechanic, capable of the finest instrument construction if he had suitable tools, and Lord Rayleigh was such a genius in devising means almost absurdly simple for conducting experiments of the most crucial character The time spent under that benign influence must perhaps have been the most precious of all in encouraging Mallock, if indeed he needed encouragement, in confidence in first principles where difficult problems were to be met

Mallock was fortunate in having lived among a group of brilliant men in the engineering world —Brunel, Froude, Tower, of spherical engine fame, Baker, Metford and others—and with his very great mechanical skill and considerable mathematical ability and ingenuity, was ready to attack and solve problems as they arose

Perhaps the class of experiment for which Mallock showed especial genius was any in which the smallest movements, tremors, bendings or stretchings had to be determined He designed and either made himself or designed and superintended the construction, by the firms of Troughton and Sims or Adie in particular, of the beautiful instruments with which he examined tremors due to the underground railway, disturbances of St Paul's Cathedral, problems connected with the Forth and Tower Bridges and many more As a civilian member of the Ordnance Committee he wrestled with many of the problems of ballistics

Mallock was also interested in many problems in optics, and in particular he was skilled in dissection under the microscope and wrote many papers on the eyes of insects and the eyes of spiders. For his microscopical mountings Mallock made use of Styrax, on which he contributed two letters to NATURE in 1924. His optical interests naturally drew him to experiment, as so many have done, with the brilliant colours of butterflies' wings and the metallic hues of beetles.

So long ago as 1874 Mallock noticed a colour phenomenon not very conspicuous, but ready to hand for almost everyone As is well known, two sheets of wire gauze or perforated zinc laid one over the other give rise to patterns of the watered silk type but without colour. If, however, only one piece of fairly fine gauze be used and the other is the reflection in an ordinary looking-glass on which it is laid, the patterns are seen as before, but now they are coloured mainly with tempered steel colours The simple explanation is given in the *Proceedings of the Royal Society* in 1918, and it is followed by a note on the colours of tempered steel

Mallock was associated with Mr Metford in the design of rifle bullets and in ascertaining their trajectories He also carried out experiments on the extreme range of rifle bullets with Lord Cottesloe An interesting example of his ingenuity and painstaking research is to be found in his apparatus for measuring the growth of trees. For this purpose he adopted an instrument which he had formerly used for observing changes in the dimensions of cracks on St Paul's and other buildings Another of his enterprises was the design and construction with his own hands of a machine for ruling diffraction gratings This machine is now at the National Physical Laboratory

These notes refer to a few only of Mallock's contributions to physical science out of a great number Fifty-six of his papers appeared in the *Proceedings of the Royal Society* and eighty-nine contributions from him were published in NATURE.

In 1904 Arnulph Mallock married Helena Maria Caroline Finlay, of Castle Toward, Argyllshire. In his last years with rapidly increasing blindness her devotion did much to alleviate his distress, for his mind and interests remained acute but first his beloved microscope and gradually all print ceased to be available to him.

WE regret to announce the following deaths:

Dr Howard Ayers, president of the University of Cincinnati from 1899 until 1904, formerly professor of biology in the University of Missouri, on October 17, aged seventy-two years.

Prof Erwin Baur, director of the Kaiser Wilhelm Institut fur Zuchtungsforchung, Berlin, on December 2, aged fifty-eight years

Prof Edwin S. Crawley, emeritus professor of mathematics in the University of Pennsylvania, known for his work on the geometry of curves, on October 18, aged seventy-one years.

Mr Edward Evans, formerly in charge of the science classes at Burnley Municipal College, author of "Botany for Beginners", on December 23, aged seventy-eight years

Prof J Cossar Ewart, F R S, formerly regius professor of natural history in the University of Edinburgh, a pioneer in animal breeding research, on December 31, aged eighty-two years.

Prof T Swale Vincent, formerly professor of physiology, University of London, an authority on the ductless glands, on December 31, aged sixty-five years

---

News and Views

New Year Honours

THE New Year Honours List includes the following names of scientific workers and others associated with scientific work · *K C V O.:* Sir Richard Glazebrook, chairman of the Aeronautical Research Committee, 1908–33 *Knights* Dr S C. Cockerell, director of the Fitzwilliam Museum, Cambridge; Mr. G. Evans, principal of the Imperial College of Tropical Agriculture, Trinidad; Dr. Kenneth Lee, chairman of the Industrial Grants Committee, Department of Scientific and Industrial Research; Col. C. E Merrett, president and trustee of the Royal Agricultural Society, State of Victoria; Prof. Robert Muir, professor of pathology, University of Glasgow; Dr C. T. Hagberg Wright, secretary and librarian of the London Library. *C.S.I* · Brigadier R H. Thomas, lately Surveyor-General of India. *C M.G.* · Prof. R. E. Alexander, director of Canterbury Agricultural College, Lincoln, near Christchurch, New Zealand; Mr. A. Holm, lately director of agriculture, Kenya. *C.I.E.:* Lieut.-Col. A. D. Stewart, director of the All-India Institute of Hygiene and Public Health, Calcutta; Lieut-Col. Ram Nath Chopra, professor of pharmacology, School of Tropical Medicine and Hygiene, Calcutta *C B.E :* Mr. J. S Buchanan, deputy director of technical development, Air Ministry, Mr. R G Hatton, director of the Horticultural Research Station, East Malling, Kent *O B E* Mr G. H J Adlam, senior science master, City of London School, Mr. M. C. C. Bonington, lately divisional forest officer and forest development officer, Andamans, Mr. C Coles, principal of Cardiff Technical College; Mr. D. Mackay, for service in connexion with scientific exploration and survey in the interior of Australia; Prof. W. Makower, professor of science, Royal Military Academy; Dr. P. D Strachan, superintendent, Leper Settlement, Botsabelo, Basutoland; Mr. H B. Thomas, deputy director of surveys, Uganda Protectorate; Mr. A. H. Unwin, conservator of forests, Cyprus. *M.B.E.*. Mr. A. S. Buckhurst, assistant in the Plant Pathological Laboratory, Harpenden; Mr. B. J. Hartley, district agricultural officer, Tanganyika Territory; Mr. C. A. Pinto, curator in the Zoological Gardens, Lahore, Punjab; Mr. M. J. S. Rosair, extra assistant conservator of forests, Burma,

Science News a Century Ago

WHEN we were arranging for the publication during 1934 of notes on topics and events of scientific interest week by week a century ago, and of industrial changes or incidents in public affairs having contacts with science, we invited several contributors familiar with particular fields to send us occasional notes for this new "Calendar" of past occurrences. One of these contributors, who has special knowledge of social and political subjects, has carried his mind back to the beginning of the year 1834, and has sent us what might have been editorial comments upon some matters then under discussion. The columns of "Science News a Century Ago", which we propose to publish throughout the year, will not usually be of the nature of comments but rather selected notes from papers or other publications during 1834. There is, however, so much of interest in our correspondent's retrospective remarks on the first day of that year that we have no hesitation in reproducing them below. The notes accurately represent the atmosphere at the time, and they remind us, among other things, that the United States had its gold problem then as now, and also that Empire communication as we know it to-day had no existence then.

January 1, 1834

"IT is natural on New Year's day to look both backward and forward—to take stock, and even to speculate as to the future. This coming year will bring the commencement of the fifth year of the reign of His Gracious Majesty King William IV, and it finds that eminent Whig, Earl Grey, who some two years ago piloted the Reform Bill to the Statute Book, still in the saddle as Prime Minister. Perhaps the most notable piece of legislation during the year which has just closed was the enactment of the abolition of slavery in Great Britain and its Colonies, despite the opposition of that rising hope of the younger Tories, Mr. William Ewart Gladstone, M.P. for Newark. Probably a century hence this measure will be regarded as one of the boldest and most enlightened efforts of the Reformed Parliament, as well as one of its earliest. Who can tell?"

"LOOKING abroad, we cannot fail to be interested in what goes on in the United States of America. Their recent severance from the British sovereignty, and their close ties of consanguinity, militate against indifference to their welfare in this country. Like most young communities, they have their own troubles to face; and, economically, the welfare of the whole world has been adversely affected by the prolonged Napoleonic wars. We feel the pinch here, even yet, most acutely, but our economic fabric is more firmly established than theirs. It is an object-lesson in the far-reaching effects of these factors that this overseas community, situated so far from the seat of the Napoleonic conflagration, is nevertheless so seriously affected. American citizens continue to be agitated by the contest which began last year as to the legality of the conduct of their President in withdrawing the public deposits from the National Bank. Meanwhile, the importation of gold into the States has assumed unprecedented proportions since January, 1833. Some there are who attribute all these happenings to a republican form of government; but that is probably too sweeping a generalisation. The States are young, vigorous, and are as yet developed to nothing like their full extent. On the other hand, many believe that they have before them a future the brilliance of which has never been matched in the Old World. Time alone can show. Anyway, these happenings are of absorbing interest, and make us increasingly impatient for the arrival of each sailing packet with mails. In some quarters this impatience takes the form of suggesting that matters would be improved if the new motive agent—the steam engine—could be brought to such a state of perfection as to replace sailing ships by steam ships; but that day is not yet, and the Atlantic is a turbulent piece of water to be conquered by so new an invention."

Centenary of Philipp Reis, 1834–1874

ON January 7 occurs the centenary of the birth of the German physicist, Johann Philipp Reis, one of the earliest pioneers of the telephone. Reis was born in Gelnhausen, and died at Friedrichsdorf near Homburg on January 14, 1874 at the early age of forty years. Left an orphan, he had to struggle against many difficulties and it was while an apprentice to a painter that he laid the foundation of his knowledge of chemistry and physics. Eventually he was offered a post as a teacher at the Institut Garnier in Friedrichsdorf, which he had attended as a boy. It was in his own private workroom that he made the apparatus which he called the "Telephon". His work was based on the true theory of telephony, and he probably designed ten distinct forms of transmitter and four forms of receiver. On October 26, 1861, he exhibited his apparatus before the Physical Society of Frankfort-on-Main and a year or two later lectured on it at Giessen. His apparatus was also placed on the market, and when D. E. Hughes went to Russia in 1865 in connexion with his printing telegraph, he took one of Reis's telephones with him and exhibited it to the Emperor Alexander II at Czarsko Zelo. But in spite of the correctness of his views and his ingenuity, Reis failed to impress others of the value of his invention. Towards the end of the 'sixties he was attacked by consumption and this led to his early death. He passed away entirely unnoticed, but after the telephone came into common use his country attempted to make some amends for the neglect he had suffered, and the Government erected a monument over his grave in the cemetery at Friedrichsdorf. His biography was written in 1883 by Silvanus Thompson, and on January 7, 1884 the Electrotechnische Gesellschaft of Frankfort held a special meeting followed by a banquet to commemorate the fiftieth anniversary of his birth.

Science and Psychical Research

IT was suggested in a leading article in NATURE of December 23, that investigations in the field of abnormal psychology, and the alleged physical phenomena said to accompany particular states of mental dissociation, might appropriately be taken up by a department of a university or other responsible scientific institution as subjects of post-graduate research. Since then we have received a circular relating to the formation of a body with the title of the International Institute for Psychical Research, "for the furtherance of knowledge in regard to psychic phenomena". The president is Prof. Elliot Smith, and two of the vice-presidents are Prof. Julian Huxley and Prof. E. W. MacBride. The chairman of the executive committee is Mr. J. Arthur Findlay, a well-known business man in Glasgow, whose book "On the Edge of the Etheric", published last year, described a series of sittings with a Scottish "direct voice" medium. Judging from this book, Mr. Findlay has little conception of the critical attitude of science towards the evidence which he presents and the explanations he gives of the phenomena he describes. In the words of our reviewer of his book: "But from reading Mr. Findlay's records the scientific method might be thought not to exist. He seems to have no appreciation of the implications underlying many of his remarks; no desire to see the phenomena described in accurate and scientific terminology."

Perhaps the men of science who have become office bearers in the new organisation will be able to see that whatever investigations are undertaken are more in accord with what science demands than are those the explanations of which are accepted by Mr. Findlay. In any event, we need scarcely say that we do not regard the new body as satisfying the conditions of psychical research in a university or similar institution referred to in the leading article in our issue of December 23. Its aims and intentions do not seem to us to differ essentially from those of the Society for Psychical Research or from Mr. Harry Price's National Laboratory for Psychical Research.

The Sea-Fish Commission

In accordance with the provisions of Section 5 of the Sea-Fishing Industry Act, 1933, the Secretary of State for Home Affairs, the Secretary of State for Scotland, and the Minister of Agriculture and Fisheries, have appointed a Sea-Fish Commission consisting of the following: Sir Andrew R. Duncan (chairman), Viscount Wolmer, M.P., Mr. Francis Beattie, Mr. Edwin Fisher, and Mr. Lawrence Neal. We note with regret that no man of science has found a place on this Commission, notwithstanding that some of its functions make scientific knowledge desirable—particularly piscicultural knowledge. To emphasise this desirability, it may be mentioned that the functions of the Committee will include the investigation of matters relating to the storage and treatment of fish after landing; and it is also inevitable that pre-landing problems will call for investigation. It is most disappointing that the tendency to ignore scientific workers in the personnel of various kinds of commissions and committees should still persist; it is the more difficult to understand when we remember that some members of the Cabinet have hitherto shown themselves to be scientifically minded.

"Codex Sinaiticus"

An appeal to the public for the amount necessary to acquire the "Codex Sinaiticus" for the British Museum could not fail to meet with a generous response, especially when backed by the offer of the Government to provide an amount equal to that raised by public subscription up to a limit of £50,000. The unique place of the Bible in English life and literature renders it peculiarly appropriate that of the two oldest and most valuable sources of the Greek text, the "Sinaiticus" and the "Vaticanus", one should find an abiding resting place beside the later "Alexandrinus" in the British Museum, while the other lies in Rome. The price to be paid to Russia is undoubtedly large, even though the method of payment will lighten the burden; but it cannot be held too high for the enhanced prestige which it will confer on Britain's greatest national museum and the increased opportunities it will afford British scholarship in biblical studies, which already stands high. The crowds which thronged the British Museum in the days following the Christmas holidays, for a brief glimpse of the manuscript—by the end of the week there had been 20,000 visitors—and the readiness with which small subscriptions poured in, were an eloquent testimony of the extent to which the imagination of the public outside scholastic and learned circles had been touched by the interest of this document of almost unique importance in the history of civilisation.

Archæological Exhibitions at the British Museum

Two loan exhibitions were opened on January 4 in the Department of British and Mediæval Antiquities, British Museum, at the head of the main staircase, containing respectively pre-Crag flints from Suffolk and palæoliths from the Raised Beach and Coombe Rock of Sussex. Mr. Reid Moir's exhibit is intended to show at least four periods, indicated by different patinations, for the rostro-carinates and other types from the Bone-bed at the base of the Crag; and one example in particular, which has a sandy deposit adhering, is held to prove its flaking prior to the Diestian deposits of the Lower Pliocene. Excavations by Mr. J. B. Calkin at Slindon Park, between Chichester and Arundel, have produced a series of worked flints which can be dated geologically, as some (mostly rolled) were found in the upper level of the Raised Beach there (surface level 135 ft. O.D.), others on the top of the Beach and in the lower part of the Coombe Rock above it. Sufficient specimens have been found to prove that the Raised Beach dates from late St. Acheul times, and the Coombe Rock covered a Levallois working-floor as at Northfleet. The Raised Beach a little south, at a height of 80-90 ft. O.D., has not produced enough to establish its identity.

Archæological Exploration in Persia

MUCH as it may be regretted that the British School of Archæology in Iraq (Gertrude Bell Memorial), in accordance with the decision announced at the end of last season, will not itself be responsible for expeditions of archæological exploration in its special province, pending more satisfactory arrangements under the antiquities laws of the country, the announcement of the grant of £500 from the funds of the School to Sir Aurel Stein towards the cost of excavating mounds in south-western Persia will afford archæologists some measure of consolation for the suspension of activities in northern Iraq The archæological work which Sir Aurel proposes to carry out with the assistance of this grant is in continuation of certain investigations which he has made during the past two seasons in south eastern Persia, where a number of early sites were examined He will cover a field in which it is anticipated that much needed evidence will be obtained bearing on the relations of the early culture of Elam and possibly, it is hoped, the relationship of the Indus valley civilisation to that of western Asia—at the moment the most intriguing of the problems of Middle Eastern prehistory It is also announced that the British School has made a grant of £100 towards the expenses of the short season of excavation at Ur which is now opening

Prehistoric Art in the Libyan Desert

SHOULD preliminary announcements be confirmed by subsequent examination of the evidence, a further link in the relations between the prehistoric art of northern Africa and the Bushman art of South Africa is afforded by discoveries made by Dr Leo Frobenius in the Libyan Desert Dr Frobenius, who has just returned from his eleventh expedition to Africa, reports, according to a Frankfort dispatch in the *Times* of December 28, that he has discovered in the Auwenat massif a centre of supplies for the stone implement factories of various parts of North Africa, with evidence in the form of rock drawings, stone tools and traces of pottery of two distinct cultural periods, the older coming from Lower Egypt in the north, the later, of a character hitherto unknown, coming from the south Moving south to the oasis of Selimah in northern Kordofan, Dr Frobenius discovered a new southern culture with a ceramic industry dating from between 6000 and 4000 B C in an area which he regards as having been the valley of a third or 'Yellow' Nile On the route to this centre, 44 stone implement factories were discovered as well as several hundred rock-drawings, representing men and animals engaged in various activities It is maintained that these discoveries throw a new light on the relations of the art of North Africa, East Spain and South Africa, while the dating of the 'factories' makes it possible to determine the direction of culture drift

Presentation to Sir Herbert Jackson, K.B.E., F.R.S.

THE Council of the British Scientific Instrument Research Association held an informal luncheon at the Connaught Rooms on December 21 in honour of Sir Herbert Jackson, who occupied the position of Director of Research of the Association from its beginning in 1918 until July 31, 1933. Some thirty members of council and friends, representing all sides of the scientific instrument industry, attended. After the luncheon, Sir Herbert Jackson was presented with a gold minute-repeater watch and a vase of carved white jade, and Lady Jackson received a pair of ivory-backed brushes and a mirror. Mr. Conrad Beck, in proposing the toast of Sir Herbert and Lady Jackson, spoke of the valuable work which Sir Herbert Jackson had done and of the friendly relations which had existed between Sir Herbert and all the members of the Association Sir Frank Smith and Mr. H. T Tizard both referred to the wide range of Sir Herbert's activities and to the wealth of helpful suggestion which he could invariably bring forward in discussions on non-technical as well as on technical matters In the remarks made by Mr R S Whipple, Mr F. Twyman and Mr. J. Hasselkus, special tribute was paid to Sir Herbert's power of inspiring self-confidence in those with whom he came into contact, and to the encouragement he had always given to instrument makers not to be satisfied with an instrument that was good enough, but to produce an instrument which was really outstanding High tribute was paid also by all the speakers, to Lady Jackson, who shares the affection in which Sir Herbert himself is held Sir Herbert Jackson, after thanking the council and members of the Association for their expressions of appreciation and for their gifts, referred to the assistance and co operation which he had received from the industry itself, and to the spirit of enterprise which animated the industry without these it would have been possible to do but little

The Physical Society's Exhibition

THE catalogue of the Annual Exhibition of Scientific Instruments and Apparatus to be held at the Imperial College by the Physical Society on January 9-11 is an octavo volume of 184 pages, the trade section occupying 148, the research and experimental section 26, and the index to the trade section 5 pages Reference to the exhibits, the stands and the firms exhibiting has been greatly facilitated by the number of the stand and the name of the firm being printed at the head of each page A considerable number of illustrations are provided, but there is still a number of firms satisfied with showing little more than the outside appearance of a piece of apparatus, for example, a box on the top of which are a handle for carrying, a small window and a few terminals, instead of a diagram of its mechanism or a view of its interior As a contrast, the descriptions in the research and experimental section are full of the information which a potential user of an instrument or a method requires in order to determine whether it will suit his purpose. In the trade section, instruments which have not been exhibited previously are marked with an asterisk and on the stalls with a red star. Many of them are connected with branches of physics which have in recent years become important in industry, for example, detectors of dangerous gases in air, X-ray equipment, colorimeters, valves and photoelectric cells. Others introduce new methods into old fields, for example, an engraving machine which seems likely to displace etching, a gas tube which leaks an electrostatic charge away if the potential exceeds a fixed value, a polish measurer working photoelectrically, and an optical tube of small diameter for examining the inside surfaces of long tubes. For this device the name "introscope" has been invented. Other new names are "grapher" for recorder, "hygrograph", "opacimeter", "stormograph" and "stormoguide" for forms of barograph, any of which may at some future date find places in a new Oxford dictionary.

The late Mr. W. W. Ouless, R.A.

THE death of the distinguished portrait painter, Mr. W. W. Ouless, on December 25, at the age of eighty-five years, recalls his skill in the portrayal, in much faithfulness, of many well known men of science. An oil painting of Charles Darwin, a treasured possession of the family, was executed in 1875, and a replica by the artist himself hangs in Christ's College, Cambridge. Considered by Darwin's children to be an outstanding presentment, it was etched very successfully by M. Rajon. It is recorded in the "Life and Letters" that the portrait was finished at the end of March 1875, that Darwin felt the sittings a great fatigue in spite of Mr. Ouless's considerate desire to spare him so far as was possible. In a letter to Sir Joseph Hooker, Darwin remarks, "I look a very venerable, acute, melancholy old boy; whether I really look so I do not know." Another portrait by Ouless was of Sir William Bowman, F.R.S. (1816–1892), eminent in ophthalmic surgery. Bowman's admirers at home and abroad specially engaged the services of Ouless for this work, whilst at the same time they arranged for a reprint of all his scientific treatises, with Prof. Burdon Sanderson and Mr. Hulke as supervisors of the issue. In 1928 Ouless painted a portrait of Sir Arthur Keith.

Asiatic Society of Bengal

ON January 15, 1934, the Asiatic Society of Bengal, which was founded under the name of the "Asiatick Society", on January 15, 1784, by Sir William Jones, will reach the age of a hundred and fifty years. The Society was founded to inquire into the history, civil and natural, the antiquities, laws, arts, sciences and literature of Asia, and during its long existence its usefulness has spread far and wide, and it has to its credit a wonderful record of achievements. The president and council of the Society have decided to celebrate, on January 15, the 150th anniversary of this foundation. The anniversary programme will consist of a conversazione in the Indian Museum, and a banquet in the hall of the Society, followed by a special anniversary meeting to receive addresses from learned societies and to elect a number of honorary anniversary members of the Society. In connexion with the centenary celebration in 1884, a volume depicting the progress of letters and science during the preceding hundred years was published; and it has been decided to undertake the preparation of a special volume on similar lines covering the period of the last fifty years.

The Electronic Organ at Poste Parisien

AMONG the many applications of the thermionic valve is the invention of a new type of organ, which makes use of valve-produced electrical oscillations converted into sound through the agency of a loud-speaker. Many types of such 'electronic' organs are being developed in different parts of the world and some of these are already being used for broadcasting purposes. An illustrated description of this type of organ installed at the Poste Parisien broadcasting station is given in the *Wireless World* of December 22. This organ has three manuals, each of four and a half octaves, together with two and a half octaves of pedals, making a total of about two hundred notes. For each of these notes a three-electrode valve is provided with its oscillatory circuit, comprising a fixed condenser and an iron-cored inductance, tuning being effected by a screw adjustment of the iron core. Another two hundred valves are fitted in the amplifiers which feed thirteen loud-speakers. A number of auxiliary instruments, mostly pneumatically operated, are fitted to produce the various noises and 'effects' required in connexion with broadcasting programmes. A notable feature of the new instrument is the 'swell' action, which is controlled by a pedal-operated rheostat applied to the whole of the organ, and not only to one or two manuals as in the case of the normal organ. The oscillations produced by the first valves are very rich in harmonics and by switching in various filter circuits the quality of the tones emitted can be varied to a considerable extent. The whole instrument is very compact and, for broadcasting purposes, the loud-speakers are not required in circuit since it is obviously unnecessary to convert the electrical into acoustical energy in order to control a wireless transmitting station.

Stream-line Form in Motor-Cars

EXPERIMENTS carried out on models in a wind tunnel by R. H. Heald, of the U.S. Bureau of Standards, shows that the trend towards stream-line form in the construction of modern cars leads at high speeds to a substantial saving of power and therefore of petrol. The tests show the air resistance of the 1933 car is more than twice that of a completely stream-lined car of the same frontal area. According to a mail report from Science Service, the tests were made on models ranging from one quarter to one fifteenth natural size with wind velocities varying from thirteen to seventy miles per hour. Some of the models were of cars of the past, but two represented cars which may be used in the future. The 1933 model had disk wheels, exposed bumpers, fenders, head-lights and a spare tyre. One of the models of the motor-car of the future had a wind-shield which made an angle of 45° with the horizontal, the chassis was rounded at the top and back and the lines were smoothly moulded. The other model had the whole upper part rounded, was blunt at the front and tapered at the back Mr. Heald computes from his results that, at 60 miles per hour, the 1922 Sedan requires 27 h.p to overcome air resistance, 26 h p is taken by the 1928 Sedan and 18 h p for the 1933 model The two stream-lined models took 8 and 6 h p respectively At 48 miles per hour it was found that the horse power expended on air resistance was halved and at 76 m p h it was doubled Mr. Heald concludes that the 1933 motor, shorn of its projecting bumpers, head lights and spare tyre, and fitted with a rounded top and sloping wind shield, would consume 10 h p less at 60 m p h and 20 h p less at 70 m p h

Earthquake Insurance in New Zealand

According to a message published in the *Times* of December 21, the Judicial Committee of the Privy Council in New Zealand has decided that, under the Workers' Compensation for Accidents Act, compensation could be claimed for the death or injury of labourers engaged in their occupations during the recent Hawke's Bay earthquake The insurance companies stated that their liability in the event of a great disaster would be so serious that they could not undertake the risk The Government accordingly introduced a measure to remove employers' liability in such cases in future This proposal being opposed, a compromise was reached limiting the total liability of the companies to £50,000 in a single earthquake or in a series of earthquakes lasting for seven days

Teaching of Biology in South Africa

An address by Dr E P Phillips on "The Teaching of Biology", read to the South African Biological Society, appears in the Society's Pamphlet No 6, 1933 Dr Phillips advocated an introduction to biology in the schools by easy stages, which would give pupils an insight into biology as a concrete whole and not as isolated facts His scheme, beginning like many others, with the differences between living and non living, leads gradually and finally to knowledge of elementary human physiology, and includes information on the great generalisations of biology The discussion which followed showed a widespread feeling that biology is not satisfactorily taught in schools, and Dr Janse placed his finger upon the weak spot in the present system when he made a plea for better trained teachers in biology

Lovibond Comparator with B.D.H. Indicators

Included in the "Catalogue of B D H Fine Chemical Products", recently received from the British Drug Houses, Ltd, London, N 1, is a leaflet describing the Lovibond comparator for use with B.D H indicators. The apparatus consists of a metal case, opening like a book, and furnished at the back with an opal glass screen and two partitions to take the test-tubes containing the liquid under examination. The standard colour glasses, nine in number, are fitted into a flat disc which may be rotated in the front half of the case, which contains two holes, in front of the test tubes. By rotating the disc, a colour glass is brought into view in front of one test-tube, containing the liquid only, through the other hole the test-tube containing liquid with the correct amount of appropriate indicator added is visible simultaneously The colour comparison can thus be quickly made The pH value of the colour appears at a third hole in the front of the case Discs are available for different indicators of pH 2 8–9 6 and also for B D H Universal indicator, pH 4-11

Eclipses of the Sun in 1934

There will be a total eclipse of the sun on February 13 14, which is invisible at Greenwich The sun will rise eclipsed over Borneo, and the path of totality runs across the Pacific Ocean without crossing any land except a few very small islands Oroluk Island, Losap Island and Wake Island lie on the path of totality No British expedition has been organised to observe the eclipse from any of these small islands In Borneo the eclipsed sun will, of course, be so low down that no useful spectroscopic observations can be made The second solar eclipse which will take place in 1934 will be an annular eclipse on August 10, also invisible at Greenwich The track crosses South Africa from Mossamedes to Inhambane

Announcements

A conference on atomic physics will be held in 1934, under the auspices of the Physical Society It will be opened by Lord Rutherford, and will probably extend over two days at least, some of the meetings being held in London and some in Cambridge

We regret that in referring to "Street Traffic Flow" by Mr Henry Watson in Nature of December 30, p 987, the price quoted was 31*s* net Messrs Chapman and Hall, Ltd, inform us that the price of the book is 21*s* net

Applications are invited for the following appointments, on or before the dates mentioned —A junior technical assistant for the Directorate of Ordnance Factories, War Office—The Permanent Under-Secretary of State (C 4), The War Office, London, S W 1 (Jan 15) A chief technical assistant to the electricity undertaking of the Metropolitan Borough of Poplar —The Town Clerk, Council Offices, High Street, Poplar, E 14 (Jan 19) A principal of the Croydon Polytechnic and Evening Institutes—The Education Officer, Education Office, Katharine Street, Croydon (Jan 31) A specialist serologist in the Union of South Africa—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, London, W C 2 (Feb 6) A principal of the Grimsby Technical Evening School—The Secretary, Education Offices, Grimsby A chemist under the Sudan Government, at Khartoum—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, London, S W 1

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Positive Electron Tracks

I. CURIE-JOLIOT, Anderson and Neddermeyer, Meitner and Philipp have been able to observe positive electrons produced by the hard γ rays of thorium C″ in lead and other elements. An attempt to explain the phenomenon has been made by Oppenheimer and Plesset, who consider it as a kind of photo-effect from the levels of negative energy, the absorption of a quantum of light energy resulting in the formation of two material particles, a negative and a positive electron. A pair of these electrons, formed in the gas of a Wilson chamber, is to be seen on one of the photographs published by Curie-Joliot[1].

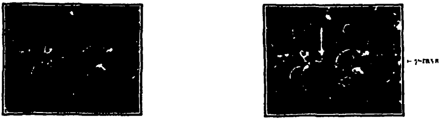

FIG. 1. Stereoscopic photographs of electronic tracks.

So early as 1931, I myself observed similar cases in the course of my researches on the Compton effect. In this, the hard γ-rays of thorium C″ were used and a Wilson chamber placed in a magnetic field. One of several pairs of stereoscopic photographs which show the phenomenon is reproduced as Fig. 1.

The origin of the track which is to be seen in the middle of Fig. 1 can be interpreted in two different ways:

1. The track may be due to a single negative electron which first moved along the arc of the larger circle (counter clock-wise), lost most of its energy in a non-elastic collision (Krammer's jump), then suffered a deviation by about 180° and finally pursued its way along a curve of smaller radius, of which a whole turn is shown.

2. The two branches may belong to two electrons of different sign issuing from the same point (which is marked by an arrow) and deviated by the magnetic field in opposite directions.

In the case illustrated in Fig. 1, as well as in three other analogous cases, the radius of the electronic tracks can be determined with comparative accuracy; therefore we are able to verify whether the energy is such as can be deduced from theoretical considerations on the assumption that the effect is due to photons of the line $h\nu = 2620$ ekilov[2].

As is well known, the sum of their kinetic energies is:

$$h\nu - 2mc^2 = 1600 \text{ ekv}$$

The table below contains the values measured for four photographs.

No.	ϵ_+	ϵ_-	$(\epsilon_+ + \epsilon_-)$	Angle formed by the two electrons	Angle formed by the γ-rays and the vector representing the sum of the impulses of both electrons
1*	1150	450	1600	20°	11°
2	1000	575	1575	22°	2°
3	1350	325	1675	90°	12°
4	675	975	1650	76°	165°

*Reproduced in Fig. 1.

The good agreement of the calculated and the observed data is much in favour of the second assumption.

In the fourth case, the first assumption does not hold at all, since it requires the collision to be accompanied by an increase of energy.

It is interesting to note that, in three cases out of four, the ratio ϵ_+/ϵ_- gives approximately the same value, something between 2 and 4, the same as in the case observed by Curie-Joliot. It appears as if, on the average, the positive electron were endowed with a considerably greater energy. For heavy elements, as in Curie-Joliot's experiments, the energy appears to be divided into nearly equal parts.

The study of the series of photographs, including the four cases of the above table, showed that the total number of Compton electrons corresponding to the line 2620 ekv. is about 700. It may be said that, in the case of light atoms (nitrogen, in particular) the number of electronic pairs is of the order of 1 per cent of the Compton electrons, in good accordance with the value computed by Oppenheimer and Plesset[3].

In general, the above-mentioned facts are in fairly good agreement with the computations of these authors as well as with Curie-Joliot's results concerning the variation of the effect with the atomic number of the element.

FIG. 2. Stereoscopic photographs of electronic tracks.

The data of Curie-Joliot seem to indicate that the ratio, number of pairs/number of Compton electrons, is proportional to the atomic number, as also follows from the Oppenheimer-Plesset theory.

II. The stereoscopic photograph reproduced as Fig. 2 represents apparently a case never observed before, namely, a pair $\epsilon_+ + \epsilon_-$, produced by a β particle. On the left is seen the track of the primary particle (ϵ_-), at the end of this track, marked by an arrow, two new tracks can be observed belonging to comparatively slow electrons emitted in opposite directions and deviated by the magnetic field in a different way. Each of the two electrons possesses an energy of about 100 ekv. The energy of the primary electron does not allow of very accurate evaluation, but it is sure to approach some 1200 e v. (E) The energy balance is thus seen to be correct.

$$E = 2mc^2 + \varepsilon_+ + \varepsilon_-$$

(After collision, the kinetic energy is carried only by one of the two negative electrons which take part in the process)

During the impact, the impulse of the primary particle is wholly passed on to the nucleus and the latter acquires sufficient energy to produce several ionisations At the intersection of the three tracks there is to be seen a distinct thickening due, perhaps, to the 'recoil' of the nucleus

Among my remaining photographs, I have one very similar to that of Fig 1, but it is less to be relied upon, since, on it, the electronic track lies on the boundary of the illuminated region

The total length of the electronic tracks I have hitherto examined amounts to several hundreds of metres The probability of the effect is thus seen to be rather high, in any event, it is much above the corresponding theoretical value found by Furry and Carlson[4]

Assuming the above interpretation and Dirac's conception of the positron to be correct, an intense 'annihilation radiation' should be expected to take place from the anticathode under the action of an electronic beam if the velocity of the electrons exceeds 1000 ekv

Combination of Proton and Neutron

SOME time ago, experiments were made, in collaboration with Dr. L H Gray, in which the scattering of neutrons by various materials was detected, with the aid of a high pressure ionisation chamber containing nitrogen[1] The results were on the whole compatible with the view that the observed ionisation was due to neutrons scattered in all directions by elastic collisions with nuclei, and various experimenters have confirmed this[2] Measurements made with paraffin wax and liquid hydrogen (the latter kindly provided by Dr P Kapitza) showed, however, the surprising result that radiation was freely emitted at angles of 120°–180° to the direction of the incident neutrons It is clearly impossible for neutrons to be scattered at angles greater than a right angle by single elastic collisions with protons, and calculation shows that multiple scattering cannot explain the observed effects

Recently the experiments have been resumed, and the scattering in the backward direction from paraffin has been measured in terms of the ionisation produced in two high-pressure chambers filled with argon and hydrogen A given intensity of gamma-radiation produces an ionisation current twelve times greater in argon than in hydrogen, while for neutrons the ratio is rather less than unity Accordingly it was possible by comparing measurements in the two gases to distinguish between gamma-radiation and neutrons When allowance was made for the carbon present in the paraffin (by observation of the scattering from graphite) the results showed that the radiation scattered from hydrogen was entirely gamma-radiation Absorption measurements extended up to a thickness of 3 4 cm of lead indicated that the scattered gamma-radiation was heterogeneous and of mean quantum energy of two to four million volts.

No mechanism is known to account for the backward scattering by hydrogen of the hard gamma-rays present in the radiation from the source of polonium plus beryllium, and experiments with thorium C″ gamma-rays failed to show any scattering under similar conditions The most plausible way of explaining the results is to suppose that in some of the collisions between the neutron and proton, the particles combine to form H^2, the heavy isotope of hydrogen The combination will result in the emission of energy in the form of gamma-radiation, and assuming that momentum is conserved, the amount of radiation will be roughly equal to half the kinetic energy of the neutron plus the mass defect of the H^2 nucleus (about one million volts, taking the mass of the neutron as 1 0067) The energy deduced experimentally for the gamma-radiation would agree with a neutron energy of two to six million volts This is of the right order, for the majority of the neutrons from beryllium and polonium have energies between two and four million volts, and some have more.

It is to be expected that H^2 nuclei produced in this way could be observed in the expansion chamber as short tracks confined to directions within a few degrees of the direction of the neutrons It is possible from the present data to make only a very rough calculation of the number of such tracks compared with the number of recoil protons, but it is estimated that the proportion may be as high as one quarter

These experiments have been made with the active support of Dr J Chadwick, to whom I am much indebted I wish especially to thank him for preparing the polonium source, and for suggesting the interpretation of the experiments

Cosmic Ultra-radiation and Auroræ Boreales

RECORDS of the ionisation in a closed vessel, caused mainly by the cosmic ultra-radiation, have been obtained at Abisko in northern Sweden (lat. 68° 21′ N) during two periods · October 1929–July 1930 and September 1932–July 1933[1]. During the first period, a Kolhörster apparatus, placed within an iron shield 6–11 cm. in thickness (free opening upwards), was used, during the second period, a Steinke apparatus, placed within a lead shield 10 cm. in thickness in all directions, was used. Every second fortnight the Steinke apparatus recorded, however, with the shield open upwards The results of both periods have been compared with simultaneous observations of the auroræ boreales and also, for the first period, with the simultaneous magnetic records of the Geophysical Observatory of Abisko[2].

The ionisation found during auroræ of different types and of different extension over the sky of the first period is shown in Table 1. It is seen that the ionisation *increases* during auroræ and also with their extension to the southern part of the sky The material of the first period is unfortunately not great, but the indication in Table 1 of an increase of the ionisation during auroræ is strongly supported by the similar increase of the ionisation during magnetic disturbances in the same period, which was shown in an earlier paper[2].

Table 1.

Extension over the sky	Clear sky, no aurora	Homogeneous arcs	Arcs with rays	Diffuse surfaces	Pulsating aurora	All types
Northern sky	2 68(12)	2 74(11)	2 79(7)	2 95(1)	3 12(1)	2 79(20)
Southern sky		2 83(8)	2 83(19)	2 79(7)	2 88(7)	2 83(41)
	2 68(12)	2 78(19)	2 82(26)	2 81(8)	2 91(8)	(61)

The numbers are pairs of ions/c c./sec in air of 1 atm pressure
The numbers within parentheses are numbers of records

A catalogue of 757 observations of auroræ boreales (1,134 noted auroral phenomena), carried out mainly at Abisko from the end of August 1932 to the end of March 1933, will be published elsewhere[3], and the catalogue contains also the simultaneously recorded values of the ionisation in the Steinke apparatus Some results of the comparison between simultaneous auroral observations and records of ionisation are briefly collected in Table 2, further results are found in the above mentioned catalogue

Table 2

Height of auroræ in the sky	Shield open upwards		Closed shield	
	Intensity of auroræ ≥ 0 5	≥ 2	Intensity of auroræ ≥ 0 5	≥ 2
0° N-60° N	2 783(174)	2 783(127)	1 944(63)	1 945(48)
60° N 60° S	2 780(78)	2 770(53)	1 942(33)	1 937(20)
60° S 0° S	2 774(59)	2 769(28)	1 933(16)	1 928(12)
During clear sky and no aurora	2 787(66)		1 956(56)	

The numbers are pairs of ions/c c /sec in air of 1 atm pressure
The numbers within parentheses are numbers of records N = North, S = South

As is seen in Table 2, the ionisation in 1932–33 *decreased* during auroræ and also with their extension to the southern horizon and with the intensity of the auroræ (scale: 0–4) It is curious that this decrease, expressed as a percentage of the ionisation with a clear sky and no aurora, is greatest when the vessel was shielded from above by a lead shield of 10 cm. thickness, that is, for the harder radiation

V. F Hess and R Steinmaurer[4] have found mainly a decrease of the ionisation during magnetic storms in the period September 1931–March 1933 from their records at Hafelekar, near Innsbruck Like the results from the second period at Abisko (great auroral displays being always accompanied by magnetic disturbances, which probably cause the change of the ionisation) this is in "apparent contradiction" to the results from the first period at Abisko Studying Table 4 of the exhaustive paper by R Steinmaurer and H. Graziadei[5], we find that in 1931 there were 4 increases and 1 decrease during 5 magnetic storms, but in 1932 there were 3 increases and 15 decreases during 18 magnetic storms. Thus the material from Hafelekar indicates a change from mainly increasing to mainly decreasing ionisation during magnetic storms in 1931–32.

At the present time, I cannot see any other explanation of the above mentioned "apparent contradiction" between 1929–30 and 1932–33 than that some connexion exists between the ionisation and the sunspot period The last sunspot maximum occurred at 1928 4, and the relative numbers for 1929 and 1930 were 65 0 and 35 7 respectively. For 1932 the relative number was 11 1, and the sunspot minimum occurred in 1933

The mechanism of the relation of terrestrial magnetism to cosmic ultra-radiation is still unknown, but as we now know no cause why the ultra-radiation should behave in opposite ways during magnetic storms at sunspot maxima and sunspot minima, it seems to me more probable that the cosmic ultra-radiation always decreases during magnetic storms, and that the observed increase of the ionisation in 1929–30 is caused by an increased influence from the sun at sunspot maxima This influence may be either an increased penetrating radiation from the sun itself, capable of reaching sea-level, or, possibly, an increased secondary radiation of the cosmic ultra-radiation, caused directly or indirectly by the solar corpuscles, which to some extent produce the auroræ.

Certain phenomena observed by other investigators[6] seem to support this explanation. Also the minor decrease of the ionisation for the open shield during magnetic storms at Abisko in 1932–33, mentioned above, may be due to a remaining primary or secondary soft radiation from the sun, tending to increase the ionisation.

Electrolytic Concentration of Diplogen

WE have recently made some preliminary investigations of the effect of various factors on the efficiency of the concentration of diplogen by electrolysis in alkaline solution The diplogen-hydrogen ratio at various stages was determined by specific gravity measurements after repeated distillation. These measurements were carried out in pyknometers of 5 c.c. and 25 c c. capacity with an estimated accuracy of one part in a hundred thousand. In calculating the diplogen concentrations, we have used Lewis's[1] value for the specific gravity of pure D_2O and Bleakney and Gould's[2] estimate of the D/H ratio in ordinary water.

We have investigated the influence of the following factors: (*a*) the nature of the cathode metal, (*b*) the concentration of the electrolyte, (*c*) the temperature of the electrolyte, and (*d*) the current density at the cathode. We have expressed the efficiency of the separation by the factor α, defined by Lewis and Macdonald[3] by means of the equation

$$d \ln D = \alpha\, d \ln H \qquad (1)$$

A correction was made for evaporation and the maximum error in our values of α is estimated to be $\pm$ 0.05. The following results were obtained:

Effect of Cathode Metal

Stage of concentration D/H 0.1–0.3 per cent

Cathode	Electrolyte	α
Ni	1 per cent NaOH	0.22
Pt	,,	0.19
Cu	,,	0.19

Effect of Concentration of Electrolyte

Stage of concentration D/H = 0.1–0.3 per cent

Cathode	Electrolyte	α
Ni	1 per cent NaOH	0.22
Ni	8 per cent NaOH	0.20

Effect of Temperature

Stage of concentration D/H 0.25–0.5 per cent

Cathode	Electrolyte	Temperature	α
Ni	2 per cent NaOH	10° C	0.23
Ni	2 per cent NaOH	100° C	0.26

Effect of Current Density

Stage of concentration D/H = 0.05–0.15 per cent

Cathode	Electrolyte	Current Density	α
Ni	1 per cent NaOH	10 amp./cm.^{2}	0.18
Ni	1 per cent NaOH	0.07 ,,	0.27

The most striking feature of these results is that the factor α is unexpectedly insensitive to the conditions of electrolysis. Neither the temperature nor the nature of the cathode metal appears to have any effect on the efficiency of separation, and it is doubtful whether the small difference observed in the current density experiments is greater than the experimental error.

It may appear strange that the efficiency is not affected by the differences in hydrogen over-voltage of the metals employed. Such a state of affairs is, however, in accordance with the theory of over-voltage advanced by Gurney[4]. He derives the following expression for the rate of discharge of hydrogen ions at an inert electrode:

$$\ln i_H = \frac{E_0 - E_1 + \epsilon V}{\gamma k T} + \log T + \text{constant} \qquad (2)$$

where i_H is the current density, E_0 is the neutralisation energy of an H_3O^+ ion in its lowest energy state by an electron, E_1 is the work function of the metal, ϵ is the electronic charge and V is the applied cathodic potential; γ is a correction factor a little greater than unity. The discharge of diplogen from the ion DH_2O^+ at the same cathode is governed by an exactly similar expression except that the value of E_0 will be different in the two cases. The nature of the cathode should therefore have no effect on the ratio i_D/i_H, in agreement with our results.

The actual value of i_D/i_H ($= \alpha$) is given by the relation

$$\ln \alpha = \ln \frac{i_D}{i_H} = \frac{(E_0)_D - (E_0)_H}{\gamma k T} \qquad (3)$$

The difference in the E_0 values in the two cases depends on the difference in zero point energy of the two links O–H and O–D, which has been calculated by Sherman and Eyring[5] as 1,400 calories per mole. The insertion of this value in equation (3) leads to our observed separation coefficient (which agrees with that found by Lewis[3]), if γ is given the plausible value of 1.4. It may be noted that on the basis of equation (3) the influence of temperature on α over the temperature range studied is just within our present experimental error, but could be observed with a slight increase in accuracy.

The above results are provisional, and more accurate investigations are in progress.

Catalytic Hydrogen Replacement and the Nature of Over-voltage

IN NATURE of December 16, 1933, J. Horiuti and M. Polanyi state that they have found that the replacement of heavy hydrogen in water under the catalytic influence of platinum black is faster in pure water than in either acid or alkaline solutions, and suggest that these observations "seem to settle the question" of the nature of the inertia which is responsible for the hydrogen over-voltage at platinum electrodes. There are, however, a number of other possibilities besides the two mentioned by Horiuti and Polanyi. I need only mention one, namely, that the effect of the acids and bases may be merely to cause a partial coagulation of the particles of the platinum, thus reducing the area available for the catalysis. Until such possibilities have been excluded, no definite conclusions as to the mechanism of the process can legitimately be drawn and it certainly appears to be extravagant to suggest that the experiments settle the question of the hydrogen over-voltage.

Reaction Rates of the Hydrogen Isotopes

IT seems to be generally assumed that diplogen will always react more slowly than hydrogen. As I may partly be responsible for this view[1], I should like to point out that this is not always correct. Lower reactivity of diplogen compared with hydrogen results mainly from two causes: (1) the existence of zero point energy; and (2) the quantum mechanical leakage of particles through energy barriers. Whilst the leakage through the barrier is always greater for the hydrogen than for the diplogen atoms, the effect of the zero point energy may occasionally favour the reverse ratio. I will confine myself to one special case, as the general treatment will be published shortly by C. E. H. Bawn and G. Ogden. Compare the reaction of a free hydrogen and a diplogen atom; in the initial state the atoms possess no zero point energy and their energies will be equal. However, at the top of the barrier there will be a zero point energy present[2], and this will be greater for the complex reacting with the hydrogen atom than for that reacting with the diplogen atom The effect of the zero point energy at the top of the barrier is, therefore, to increase the activation energy of the hydrogen atoms to a greater extent than that of the diplogen atoms.

New Developments in *Gammarus chevreuxi*, Sexton

IN the course of some experiments on eye-colour in the amphipod, *Gammarus chevreuxi*, a number of mated pairs were brought in to the Laboratory from the Chelson Meadow salt-marsh between February 20 and March 13, 1933 Half the specimens were placed in an incubator, kept at an approximately constant temperature of 21° C and half were put in an unheated room

The F_1 from these pairs numbered 12,164

The normal eye in the wild *Gammarus* is a compound structure, composed of a number of ommatidia, each of which is provided with five retinular cells containing black pigment, the spaces between the ommatidia being filled with white 'accessory pigment' cells It is this pigment which gives to the eye of the living animal the effect as of a superficial white network spread over a black ground In the embryo eye, the retinular pigment commences as bright red, and darkens to black before extrusion

During the twenty years of our work on this species we have never found any but black eyed animals in the wild, nor have any changes in eye-structure or in colour appeared in the laboratory cultures before the F_3 generation Lately, however, we have come to the conclusion that the character of the wild stock is changing The conditions of its habitat have altered, owing probably to the installation of new sluice gates at the outlet from the salt-marsh These being operated at infrequent intervals have caused considerable variation in the depth, temperature and salinity of the water in the draining ditches where the *Gammarus* live, and are responsible for what is probably the most influential factor in the change, namely, the great fluctuations in the numbers of the population within comparatively short periods But whatever the causes may be, we have noticed in recent experiments that not only is there a much higher percentage of variation than formerly, but a much wider range as well

For the first time, we have had colour changes in the F_1 from the wild, and, for the first time also, a remarkable example of different coloured eyes in the same animal, one eye black and the other bright red Both instances came from a dredging taken on March 13.

The first, an ovigerous female, which hatched her eggs in the cold room a few days after being brought into the Laboratory, had evidently mated with a heterozygous male in the wild, for her brood when extruded contained 2 red-eyed young and 9 black-eyed. She was then mated with three different males from the same dredging, and gave an F_1 of 62 black with the first, 37 black with the second, and 34 black with the third, the red appearing in the F_2.

The second instance, the specimen with eyes of different colours, came from one of the pairs in the incubator. This pair produced three broods, the first numbering 13 black, and the third, 15 black, died without offspring The second brood consisted of 14 black and the one-sided red specimen just referred to, which had the right eye red Fourteen reached maturity, seven black males, six black females, and the one-sided red, a male The blacks, mated together, gave in some pairs an F_2 of black and red in a 3 1 ratio, and in others, all black offspring

The one sided red male's matings show that it behaves genetically as a heterozygous black It was mated with two of the heterozygous black females, giving 77 black and 22 red with one, and 25 black and 12 red with the other It was then tried with three of the F_2 red females and gave with the first 11 black and 10 red, with the second 10 black and 11 red, but with the third (which was from its own mating with one of the black females) the proportions were unexpected, 2 black and 20 red

Not one of the offspring of the one-sided red, nor of the thirteen blacks of its brood, has had eyes of different colours, either in the F_2 or the F_3, so far

With heterozygosity definitely proved to exist now in the wild stock, it seems strange that no red-eyed specimens have yet been found in the ditches Dredgings have been made throughout the year, and all the animals captured, 5015, examined for eye colour, but all without exception had the normal black eyes typical of the species

Endocrine Factors in the Causation of the Creatinuria of Pregnancy

THE following points emerge from the experiments of Schrire and Zwarenstein[1]

1 Castration of male and female rabbits produces an increased excretion of creatinine In females the excretion of creatine is not affected

2 Injection of gonadal extracts reduces the high creatinine of castration to the pre castration level Injection of anterior pituitary extracts into normal animals produces an increased elimination of creatinine

3 The castration effect on creatinine is a secondary effect due to functional hypertrophy of the anterior lobe of the pituitary, which occurs as a result of gonadectomy

The experimental data are explicable on the following assumptions. The pituitary stimulates the formation of creatine. The transformation of creatine to creatinine in the muscles is controlled by the gonads in that they inhibit the formation of creatinine. In the gonadectomised animal, as a result of anterior pituitary hypertrophy, more creatine becomes available, and owing to the absence of the inhibitory activity of the gonads it is completely eliminated as creatinine

A typical case of acromegaly (male, aged forty-five years) investigated by Mirvish and Schrire[2] excreted 0 59 gm creatine, 2 58 gm. creatinine in 24 hours (average figures). The presence of creatine in large amounts, and the increased excretion of creatinine, can be explained as follows: Hypertrophy of the anterior pituitary leads (*a*) to increased formation of creatine and (*b*) to stimulation of the gonads. The latter factor increases the inhibitory action of the gonads on creatine–creatinine change with the result that some of the excess creatine appears in the urine as such, and some appears in the form of increased creatinine.

On the basis of the above considerations, the following hypothesis is advanced as an explanation of the creatinuria of pregnancy. Functional hypertrophy of the anterior lobe of the pituitary occurs in pregnancy, and this leads to essentially the same processes as in acromegaly except for the effect of a persistent corpus luteum. It is suggested that the corpus luteum reinforces the inhibitory action of the ovary on the transformation of creatine to creatinine so that all the excess creatine is excreted as such and the creatinine level remains unchanged.

Thus, in the castrated animal the inhibitory action of the gonads is nil, and all excess creatine is excreted as creatinine. In pregnancy the inhibitory action is a maximum, and all excess creatine is eliminated as such. Acromegaly presents an intermediate condition which leads to the appearance of creatine in the urine of males, and an increased excretion of creatinine. In all these conditions the hypertrophy of the anterior lobe of the pituitary, and the production of excess creatine, is a common factor, but the differences in urinary output are due to quantitative differences in the amount and extent of the inhibitory action of the gonads on the transformation of creatine to creatinine in the muscles.

It is possible that the endocrine factors outlined above, coupled with the probability that the immaturity of the young animal's muscles is associated with a defective capacity to utilise creatine (Powis and Raper[3]), may supply a basis for an explanation of the creatinuria during growth.

The hypothesis suggested rests only partly on experimental evidence but it indicates the lines on which future inquiry may profitably be based.

Experiments on Evaluation of Helium from Radioactive Minerals and Rocks

IT is very well known that the rate of loss of helium from different radioactive minerals and rocks depends on the dimensions of the surface and on the temperature. When minerals are finely ground, or heated to a high temperature, there is a considerable loss of helium, which can attain about 90 per cent when both of the above mentioned factors are concerned.

Theoretical considerations make it very probable that the amount of helium lost from minerals depends in some cases also on the composition of the gaseous phase which surrounds the mineral or the rock sample. We have proved this assumption experimentally and the results obtained seem of sufficient interest to be recorded.

The amount of helium evolved from different minerals at a given temperature, if this temperature is above a critical one, depends on the presence of hydrogen in the gaseous phase and is the greater the higher the partial pressure of hydrogen. The rate of loss of helium from uraninite (pitchblende) during two hours' heating at 500° is as follows:—*in vacuo*, 10 per cent.; in atmosphere of hydrogen at 25 mm. pressure, 17 per cent; in atmosphere of hydrogen at 100 mm. pressure, 36·5 per cent; in atmosphere of hydrogen at 500 mm. pressure, 60 per cent. The rate of loss from a mineral of the family of euxenite (chlopinite) at 900° is:—*in vacuo*, 13·3 per cent.; in atmosphere of hydrogen at 250 mm. pressure, 56·1 per cent.

The influence of hydrogen upon the rate of evolution of helium from minerals is so well marked that small amounts of hydrogen in a gas mixture can be detected by means of this process. A more detailed description of these experiments, and the discussion of the results obtained, will be given in another paper.

Crystal Absorption by Substrates

IN the course of recent experiments it was found, in agreement with French[1], that suitable polishing destroys the crystalline structure of metallic surfaces. In addition, new and remarkable facts came to light. Thus, we have observed that when certain metal vapours are condensed on a substrate consisting of a polished metallic surface, crystals are formed which, however, rapidly disappear at room temperature. This is borne out by the fact that, whilst the freshly formed deposit gives rise to a characteristic electron-diffraction pattern, the rings more or less rapidly disappear, and that without any appreciable broadening effect. On the other hand, in the case of a crystalline but otherwise similar substrate, the diffraction pattern yielded by the deposit is permanent.

Thus, the stability or otherwise of the deposit crystals is determined by the condition of the substrate. For example, we have found that zinc vapour suitably condensed on a cool, polished copper surface gives rise to an initially brilliant and well-defined electron diffraction pattern which rapidly fades away, to become extinct within a few seconds. In one such experiment, twelve successive zinc layers were deposited. With each layer except the last the initial crystalline structure vanished at a rate decreasing with each successive deposit. Zinc deposited under otherwise similar conditions, but on sputtered or etched copper, or on a previously oxidised and then reduced copper surface, formed a crystalline film the structure of which remained unchanged. It seems to us that these facts afford direct experimental proof of the existence of the Beilby layer.

Observations of Water Trajectories in the Open Sea

DIRECT observations of continuous movements of water masses in the open sea do not appear to have been carried out before. We have, for this purpose, for some years been using free drifting current-crosses, followed by our research steamer the *Skagerak*. The crosses are made from two sheets of corrugated iron, intersecting at right angles, with the line of intersection vertical, and presenting an area to the current of approximately one square metre They are suspended from a cylindrical buoy of small dimensions drifting at the surface with its axis vertical. The buoy carries a very light rod projecting upwards with a small electric lamp at the top, of the type used by drifters for their nets. By varying the length of the thin wire rope by which the cross is suspended from the buoy, one may study the water movements in different depths, since the small resistance due to the surface buoy does not affect the movements of the cross to any large extent, so long as the current below is not too weak relatively to the surface current. The positions of the buoy are observed at intervals of an hour or less by bringing up the ship as close to the drifting system as possible, without interfering with its movements. In daytime, with moderately strong currents, the movements of the buoy are followed from the ship at anchor by means of a Zeiss tele-meter. Such drifting systems have occasionally been followed right across the Skagerak from Skagen to the lighthouse Måseskär on the Swedish coast

Last summer this method was found particularly useful for studies of the rotating currents discovered from the *Skagerak* in the central Baltic[1] In order to determine the shifting positions of the drifting system as accurately as possible far from the shores (lat 58° 01′ N, long 20° 30′ W), three large surface buoys carrying electric torches were anchored a few kilometres apart, by means of which the bearings of the ship following the drifting cross could be accurately found With the cross at 10 metres below the surface the trajectories from thirty hours' observations were found to form two beautifully smooth loops, showing, beside the rotatory current, a general displacement towards the S S W. The rotating vector turned by a little more than 720° in the same time The period thus is about fourteen hours, in good agreement with previous observations on these 'inertia currents' The details will be published in *Svenska Hydrografisk-Biologiska Kommissionens Skrifter*

Ionospheric Investigations in Low Latitudes

DURING the recent expedition of the "Consiglio Nazionale delle Ricerche" in Eritrea for studying cosmic rays, I made many observations by the echo method on the state of the ionosphere at Asmara (lat 15° 20′ N, long 38° 55′ E), from September to November 1933 The most important results are as follows

The limiting wave-length for the vertical reflection in region *F* during the daylight hours reaches a minimum value between 26 and 28 metres towards six o'clock in the afternoon (local time) and not at noon as in the middle latitudes. In correspondence with this maximum of ionic density, waves between 140 m. and the limiting wave are reflected at heights which differ by less than 5 km.: this shows the formation of an extremely thin ionised layer

The most interesting phenomenon that has been revealed from these observations is that, toward two o'clock in the morning, a very strong decrease of the limiting wave-length in region *F* is frequently noted it may pass from 60 m to 40 m. (for the extraordinary ray) in an hour or two. Simultaneously, the virtual height of reflection decreases for all wave-lengths. After having shown this secondary nightly maximum, the ionic density decreases until about half an hour before sunrise, and then increases again during daylight Another striking feature of the ionospheric conditions is the violent fading and complexity of echoes which accompany these nightly increases of ionic density. On many occasions I have observed the simultaneous rising of a particular type of atmospherics with continuous rustling

Region *E* presents a maximum of ionic density, which is always less than that of region *F*, and it is also sometimes subject to nightly increases of ionic density, chiefly in the early hours of night

The observed phenomena, especially the nightly increases of ionic density in region *F* and the occurrence of the daily maximum about six hours after the sun's radiation reaches its maximum, having regard to the geomagnetic latitude of Asmara (11° 30′), cannot be explained as due to electrified corpuscles from the sun or other cosmic origin, which may be able to ionise the high atmosphere At present, the only logical suggestion which can be formulated is C T R Wilson's[1] that the effects are due to the ionisation produced by the electric fields of thunderstorms, which undoubtedly reach very high values in tropical regions

Vibrational Energy Levels of Hydrogen Cyanide

THE infra red spectrum of HCN vapour has been examined with fairly high dispersion in the region near 2μ The following bands were observed.

Band	Position	Character
$\nu_2 + \nu_3$	4005 6 cm^{-1}	perpendicular
$\nu_2 + 2\nu_1$	4993 9	perpendicular
$\nu_1 + \nu_3$	5405 0	parallel
$2\nu_3$	6523 5	parallel

The band at 5405 is somewhat distorted, due to water vapour absorption in the same region, and its position is accurate only to within a few wave numbers The discovery of the two perpendicular bands makes it possible to construct the complete vibrational energy level diagram of the normal molecule with a high degree of precision. In a report to appear in the near future the detailed analysis will be presented, and also the application of the results to the determination of the thermodynamic potentials of hydrogen cyanide.

Research Items

Polychrome Jewellery in Kent A new view of the origin and dating of the garnet-inlaid jewellery from Teutonic graves in Kent is put forward by Mr T D Kendrick in *Antiquity* for December According to the generally accepted view of the two groups into which this jewellery falls, one (Style *A*) characterised by cloisonné and filigree, in which there is no chip-carving and niello is rare, is regarded as later than the class (Style *B*) in which chip-carving and cast settings are the rule, niello is common, and there is no filigree and no cloisonné The earlier, Style *B*, is dated as from the early sixth century, while Style *A* is assigned to late sixth or early seventh century, one view holding that the latter represents Jutish supremacy under Ethelbert It is here suggested, however, that a substantial part of the polychrome jewellery belongs to an earlier Kentish population than the Jutes of Ethelbert, and that the two groups are contemporary and belong to the archæology of the Jutish invasion, with a central date at about A D 500 It is clear that Style *A* had a cultural background of its own, remarkable for its 'luxury' or foreign aspect, being associated with Coptic bronze bowls, amethyst beads and cowries It is also associated with 'British' hanging bowls Its distribution in the main is along Watling Street, while Style *B* is found chiefly in Thanet and the Sandwich country While Style *B* may well be Jutish, it is suggested that Style *A*, which exhibits unrivalled workmanship and is clearly a distinct culture, was of British origin The distribution of the two cultures is explicable on the supposition that for a time the Dover road continued to be held by British when all other lines of communication had been blocked by the Jutes and that the Teutonic settlements along the Watling Street are those not of Jutes but of miscellaneous Teutonic mercenaries called in to help keep open communications with the Continent

Rain-making in Neolithic Times Prof. L Joleaud (*Revue Scientifique*, Nov 25) constructs a pedigree for certain rites connected with rain and the supply of water in rivers, lakes and wells in north-west Africa, which extends back to neolithic times, through references in classical authors, analogies from Ancient Egypt and the rock drawings of North Africa, more particularly in Morocco and the Sahara The essential feature in the modern rites is a procession of domestic animals, especially rams and oxen, accompanied by men bearing ladles and spades and sometimes playing ball with sticks, hand or foot The beasts are decked with various ornaments and trappings, feathers, leaves, amulets, etc Both animals and men participating should urinate in the course of the ceremony and special honour is paid to the genital organs of both men and beasts. The rock-drawings of Oran, and to a less extent of the Sahara, bear witness to the neolithic origin of these rites Rams and oxen, similarly caparisoned, are shown in the drawings taking a prominent part in invocation rites In some instances, what would appear to be intended for rain is falling on the animals. Sometimes men or beasts are shown urinating or preparing to perform that act. In a cave at Cape Spartel in northern Morocco a large number of terra-cotta models of neolithic date of the genital organ of rams and bucks have been found, which, apparently, had served as idols or *ex-votos* The place of the ram, which is the most prominent animal in the neolithic rites, is taken later, at about the period of the æneolithic age in Egypt, by the bull Prof Joleaud traces the connexion of these early animal figures with animal-headed gods such as Ammon and their development into anthropomorphs

Mammals of California Dr Joseph Grinnell has compiled a catalogue of the recent mammal fauna of California in which he indicates the place of the original description, the type locality and the range of 460 species and sub-species, including four sub-species of man (Univ California Pub Zool., 40, No 2, 71-234, 1933) This number of distinct forms, which includes 220 full species, has greatly increased since the first Californian list, of 1868, with its 115 kinds, or even the 1906 list of Frank Stephens, with 276 kinds The list includes several species of non-native mammals such as the black and Norway rats, the Alexandrine rat and the house-mouse, only the first of which is relatively scarce and is confined to coast-wise cities. Equally successful in its powers of colonisation has been the Virginian opossum, first introduced by man probably about the beginning of the present century and now present in nearly all the counties of San Francisco Bay region and of the Pacific slope of Southern California

Territory in the Life of Birds The theory of territory in bird life, enunciated by Eliot Howard some twenty-five years ago and supported by the field observations of himself and others, has never gained complete acceptance, and now David and Dr Lambert Lack have formulated a reasoned argument against the wholesale application of the theory (*British Birds*, 179; Dec. 1933) Were territory a primary requirement for success in reproduction, it might be expected to be universal amongst birds. It is not universal, and many of the most successful amongst birds are colonial breeders Moreover, according to the authors, there is no good evidence that territory is important in conserving a food supply for the young Many territorial birds, like colonial birds, obtain their food, not from their own 'territory', but from a common feeding ground; they allow other members of the same species to feed in their territory; and, on occasion, even their own selected females may ignore the territory of their mate and build in that of another male. Indeed 'territory' is really nothing more than a male bird's song centre, in which he can sing and display in prominence, and since these activities are at their highest at the beginning of the breeding season, it is only at that period that territory is strictly maintained

Russian Spiders. A list of the spiders of the U.S S R., prepared by Prof D Charitonov, has just been published by the Leningrad Academy of Sciences (Katalog Russkich Paulov, *Ann Mus. Zool*, 32, 1-206) The classification adopted is that of Petrunkevitch (1928) and the list includes the names of 1,068 spiders found in Russia, with the localities and captors of each species The introduction and notes are printed in Russian and German. All records to

1930 are included, but many districts are still unsearched and a large increase may be expected. Of the 222 genera mentioned, 163 are also British, so that the work supplies a welcome addition to our knowledge of the range of many British species. It appears that more than half the Russian spider fauna belongs to four families—Linyphiidæ 261, Lycosidæ 145, Attidæ 127 and Thomisidæ 110 species, the corresponding British figures being approximately 240, 36, 33 and 34. Before long, Great Britain will be the only European country in which a recent list of the native Araneæ is not existent, a fact which should be remedied.

Biology of *Calanus*. In a contribution to the literature of *Calanus*, Dr. Sydney G. Gibbons gives an account of material collected in a restricted part of the North Sea ("A Study of the Biology of *Calanus finmarchicus* in the North-Western North Sea" Fishery Board for Scotland Scientific Investigations 1933 No. 1). Of all the copepods caught in the nets, *Calanus* predominates to a large extent in almost every haul, at certain times (May–August) the mean percentage abundance reaching 70 or more. Special attention is given to the separate stages picked out from the plankton, from nauplius to adult—eleven stages in all. The author is able to show that from the last larval stage (fifth copepodid stage), which shows no trace of external sexual characters, the perfect male or female arises. Besides this he has found a sixth nauplius stage, not before noticed, coming between the fifth nauplius and the first copepodid stages. The area investigated is difficult to compare with other regions where *Calanus* has been specially worked out. There is a very small winter population which in November consists of slowly developing late copepodid stages. By February many have grown into adults which breed, and nauplii appear. A rapid rise in numbers in April is due in the north to additions from outside, in the south from breeding of adults already there. Soon the southern section is inundated with 3rd and 4th copepodid stages from outside. The influx first affects the north, then the south, and the *Calanus* population is due both to movement from north to south and to development within the area.

Polyhedral Cells. F. T. Lewis has recently discussed the shapes of cells (*Proc. Amer. Acad. Arts and Sci.*, 68, June 1933), in the investigation of which he has employed the wax-plate reconstruction method. He states that tissues are not composed of rhombic dodecahedral cells, truncated or otherwise, for these shapes have characteristic tetrahedral angles which cells avoid. In a mass of cells of approximately uniform size, the average cell has fourteen faces of contact with its neighbours; it is a tetrakaidecahedron. Data in support of this are given for 100 cells in elder pith and in fat tissue and for 50 cells in precartilage in the tadpole of *Bufo*. In the elder pith the cells tend to be in orderly arrangement in columns, but in fat and precartilage the cells, with the same number of facets, seem piled in lawless confusion. A reconstruction shows 16 cartilage cells, with an average of 14.1 facets, which had 12–21 facets each. The author adds a surmise concerning nerve cells and neuroglia, pointing out that these two types of branching cells arise out of the primitively uniform cells of the medullary tube. Since cells formed around nuclei distributed at random are on the average 14-hedral, it may be assumed that the primitive cells of the medullary tube are of this character. He suggests that the nerve cells imbibe, grow and send out processes; the neuroglia cells become relatively shrunken. The processes of the nerve cells, one axone and the dendrites, would grow, out along the lines of least resistance, extending from the corners of the cells as shown in a model, but with the regression of the neuroglia the intracellular spaces would become large and the dendrites would not preserve their angular kinks.

Primulas in Bhutan. A very interesting account of a botanical tour in Bhutan, a State between India and Tibet, appears in No. 87 (vol. 18) of *Notes from the Royal Botanic Garden, Edinburgh* ("Botanical Tours in Bhutan, with Special Reference to the Occurrence of the Genus *Primula*", by Roland Edgar Cooper, pp. 67–118, Nov. 1933). The author visited Bhutan in 1914–15, touring the country extensively. Notes of the general distribution of vegetation are given, but the various members of the genus *Primula* received special attention. Several new species or forms are described in the paper under review, and seventeen out of the thirty-two sections of the botanical genus occur in Bhutan. The species are all described according to the classification of Smith and Forrest (1928), and are extremely useful in providing information about the natural habitats of many garden primulas.

Fungi causing Sooty Moulds. Several European mycologists have, in time past, described various fungi which produce a black, powdery mould upon the leaves of various plants. The idea that this condition was due to infection by two or more fungi had been growing, but proof is now forthcoming ("The 'Sooty Moulds' of some Australian Plants", by Miss E. E. Fisher, *Proc. Roy. Soc. Victoria*, 45, N.S., Pt. 2, 1933, pp. 171–203). Sooty moulds on plants of *Bursaria spinosa*, *Leptospermum* spp., *Myoporum insulare* and *Melaleuca* sp. have been investigated. On some hosts the mould consists of two fungi, but usually there are three types: a perithecial stage, which is often a species of the genus *Teichospora*, a pycnidial stage, and an open conidial stage. The fungi of each stage which appear upon the hosts mentioned above are described in minute detail, both as they occur in Nature and as they behave upon culture media.

Observations on a Tropical Cyclone. The *Marine Observer* of October 1933 contains an account of a particularly violent hurricane through which the S.S. *Phemius* passed on November 5–9, 1932, when on a voyage from Savannah to Colon. The description is by the observing officer, Mr. H. Nicholas. It does much to correct the impression of symmetry and simplicity sometimes conveyed by accounts of tropical cyclones in meteorological textbooks. Four barometric minima were experienced, and on one day—November 6—two lulls with phenomena characteristic of the calm 'eye' of a storm were experienced at about 2 a.m. and 4 p.m., each of which lasted about an hour. The *Phemius* lost her funnel and had derricks, lifeboats and bridges wrecked by the force of the wind, the speed of which was estimated as two hundred miles an hour, and for a long time the ship was carried by the storm in an unmanageable state. The lowest barometric minimum occurred at

8 p.m. on November 5, this being the first of the four minima, which followed a continuous and very rapid fall of pressure. The reading fell to 914.6 millibars (27.01 in.), which is 4.3 millibars (0.13 in.) lower than the previous lowest verified barometer reading recorded in a tropical cyclone, namely, in the hurricane of September 19, 1885, which passed over False Point, River Hooghly. The ship's barometer, it may be noted, had only recently been supplied by the Meteorological Office, and had been certified by the National Physical Laboratory during the previous year. On emerging into fair weather, the *Phemius* was taken in tow by a salvage steamer, and the hurricane continued northwards to cause much damage on Grand Cayman Island.

Pipe Heaters and Coolers. The report by Dr. Ezer Griffiths and Mr. J. H. Awbery on the measurements they have made at the National Physical Laboratory under the auspices of the Engineering Committee of the Food Investigation Board on the heat transfer between metal pipes and a stream of air was read by the authors before the Institution of Mechanical Engineers on December 15. It supplies more definite information than has been available hitherto on the effects of the speed and temperature of the air, the size and temperature of the pipe and its position with respect to neighbouring pipes, on the interchange of heat between air and pipe. For dry pipes the interchange is the same for the same two temperatures whether the pipe is hotter or colder than the air. If ice or snow form on a cold pipe but remain dry, the abstraction of heat from the air is the same as from a bare pipe of the diameter and temperature of the outer surface of the covering, but if water is dripping from the ice or snow the heat abstracted is increased 30 per cent. In all cases turbulence in the air stream increases the heat interchange.

Background Noise in Amplifiers. It has long been recognised that some of the background noise in valve amplifiers is due to the inherent properties of materials as they exist. In a paper read to the Institution of Electrical Engineers on December 6 by E. B. Moullin and H. D. M. Ellis, the causes that give rise to the noise are divided into two classes. There is first the spontaneous voltage in the circuit called 'thermal agitation', and there is secondly the inherent mechanism of thermionic conduction within a valve which is called the Schrott effect. The experimental work described in this paper is a continuation and amplification of the pioneer work done by other scientific workers. All the component portions of an amplifier produce spontaneous fluctuations of voltage and those harmonic components which are inside the acoustic range disclose themselves by making background noise. This noise is always a scratchy hissing noise, but the general level of the pitch rises with the frequency of the circuit. The experimental results given verify the theory. It is shown that bare wire is unsuitable for use in the early stages of a high magnification amplifier as it exhibits curious effects when it carries a current. The electric current passing from the filament to the anode of a thermionic valve is now considered to be a stream of individual electrons. The pattering of these electrons on the anode maintain it at a fluctuating potential. Since these electrons come to rest in the space charge at random intervals of time, they arrive at irregular times and so participate in the general Schrott effect. According to the authors' view, the Schrott voltage is due essentially to the anode circuit receiving current by discrete charges, and must always occur.

Collisions of Neutrons with Atomic Nuclei. Feather (*Proc. Roy. Soc.*, A, Nov.) has carried out further cloud chamber investigations on the collisions of neutrons with light atomic nuclei. The neutrons were derived from a polonium-beryllium source and the tracks were studied in oxygen, an oxygen-hydrogen mixture and a mixture of acetylene and helium chosen to have suitable properties for the working of the expansion chamber. A frequency curve of the ranges of the oxygen recoil atoms is similar to the curve for nitrogen collisions, obtained from previous work and presented here in a revised form. Few oxygen recoil atoms have a range greater than about 2.8 mm. of air. Using data of Blackett and Lees to correlate range of recoil atom with velocity and assuming that the collisions of the neutron are elastic, most of the neutrons are found to have an upper energy limit of about 4.5×10^6 volts. It is not clear whether the neutrons form a homogeneous group or a continuous distribution, since the distribution curves of the recoil atom energies are in any case continuous. The interpretation of the tracks obtained in the mixtures is complicated. The distribution curve for the acetylene-helium mixture shows a pronounced change in slope at 46 mm. range; this may be ascribed to helium or to carbon. In the former case, it would indicate the appearance of a group of neutrons of energy about 1.1 million volts—presumably produced by resonance disintegration, and in the latter case it would indicate the presence of neutrons of more than 10 million volts. The study of the brightness variation of several individual tracks indicates that they ought to be ascribed to carbon nuclei, and gives some evidence in favour of the existence of high velocity neutrons. In addition to the elastic collisions, disintegrations were observed in oxygen, and ascribed to the capture process $O^{16} + n \rightarrow C^{13} + He$, the energy relations requiring the production of a high energy γ-ray. The disintegration of carbon is very rare, if existent, only one case being found in more than two thousand photographs.

Temperature Data of Metals. Sir Robert Hadfield and the Research Department of his firm, Messrs. Hadfields, Ltd., Sheffield, have recently published a new edition of a temperature chart extending from −273.05° C. up to the temperature of the electric arc, which they give as 3,700° C. (T 6165. 1s.). The melting and boiling points of various materials are tabulated, the greatest care having been taken to ascertain the latest and most reliable data. An interesting, and unusual, feature of this chart is that the degree of accuracy with which the temperature is known in any particular case is indicated by the manner of its presentation. Thus, up to a temperature corresponding with the melting point of copper, 1083.0° C., the temperature is regarded as being reliable to within ±0.1° C., whilst at the melting point of molybdenum, 2615° C., the degree of accuracy is regarded as ± 5° C. In addition to the data for the pure results, the melting points of various refractory materials, the temper colours of steel and other industrial temperatures of importance, are recorded. The purpose of the chart is stated to be: "To present to those concerned, in convenient form, various temperature data of general interest", and in this the producers are singularly successful.

Reference Chart for the Apparent Motions of the Sun, Moon and Planets

By DR. B. K VAIDYA, Indian Institute of Science, Bangalore

THE apparent motions of the sun, the moon and the planets during the course of a year can be represented very conveniently by plotting on a single sheet of paper the right ascension of these bodies corresponding with each day of the year The planetary chart prepared in this way gives a picture of the sky for the whole year, so far as the principal members of the solar system are concerned, and besides, it shows at a glance all the planetary phenomena and the days when they occur

Fig 1 shows such a chart for the year 1934 It is not possible to include in the diagram the variations in the declinations of the objects, but this need cause little interference, as the movements considered here lie within the comparatively narrow region around the ecliptic Along with the right ascension hours on the ordinate are given the names of twelve stars in the zodiacal constellations. These stars are placed at a distance of approximately two-hour angles in succession, and lie at points which are very near the ecliptic. They serve to locate the positions of the planets, the sun and the moon at any desired day of the year.

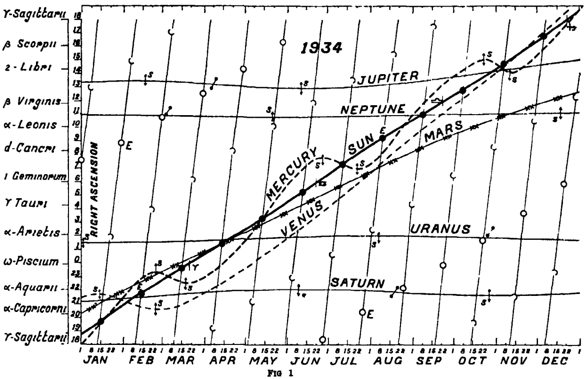

FIG 1

The most interesting types of curves are described by the two inferior planets, Mercury and Venus Their motions lie alternately above (eastern elongation) and below (western elongation) the sun's line of motion, corresponding to the periods when they appear as the evening and morning stars, respectively The greatest elongations are reached on the days when their distances from the sun line are a maximum. When their paths intersect the sun line during a forward motion they are in superior conjunction with the sun, while during a downward or retrograde course they pass through an inferior conjunction at the point of intersection with the sun line The proper dates and periods for these and other phenomena are read off on the abscissa

In other respects the chart is self-explanatory. The dates for the mutual conjunctions of the planets and for their conjunctions with the sun and the moon are given by various points of intersections The stationary points at the two extremities of a retrograde path are marked *S* The time of opposition to the sun is marked by the appropriate symbol. The moon's path, with the four principal phases, is shown by a number of slanting lines crossing the whole of the diagram The solar and the lunar eclipses are marked by the letter *E* near a new moon or a full moon. The times of the equinoxes and the solstices are indicated by the conventional zodiacal symbols.

The time of the rising or the setting of a planet on any particular day may be ascertained by finding its distance from the sun on the day in question. This distance gives directly the duration in hours for which the planet would be visible above the horizon, after the sunset or before the sunrise according to its position above or below the sun line. Thus it may be seen from the diagram that at the end of January 1934 a remarkable phenomenon occurs when the sun is closely followed by the four planets, Mercury, Venus, Saturn and Mars, the first three of these setting about half an hour and the last about an hour after the sun.

Disorientation and Vertigo

SECTIONS I (Physiology) and J (Psychology) of the British Association discussed on September 7 at a joint meeting the problems of disorientation and vertigo. Dr. J. T. MacCurdy (Cambridge) was the first speaker. He said that the most universal type of physiological orientation is the reaction to gravity. When the effective value of g is varied, there is an increase or decrease in the tension of the muscles which withstand the drag. When the direction of g is changed, there are reflex movements of the trunks and limbs which re-orient the body to g, the so-called righting reflexes. Any disturbance of these balancing reactions would upset the bodily orientation, if there were no accessory means of judging the direction of g. Such a means exists in vision.

The labyrinthine sensations, regarded generally as the most important for maintaining posture, are regarded by MacCurdy, following Garten, as the least important, and the muscle and deep pressure senses as the most important factors.

Discussing the relationship of vertigo to disorientation, Dr. MacCurdy pointed out that when the labyrinth or other parts of the balancing system are diseased, the body is physiologically disoriented, but the individual is not necessarily psychologically disoriented, if his judgment remains intact. His judgment, however, can be interfered with in three ways: either his attention may be distracted by giddiness or by his efforts to maintain his balance; or objects themselves may be viewed with difficulty because they are in motion or seen at an unfamiliar angle; or the posture-balance component of the visual perception may be absent or distorted. All these conditions involve for compensation the intellectual building up of a correct perception, which may be substituted for the usual, automatically correct reaction to g.

Dr. MacCurdy illustrated his points from the sphere of flying, and further illustrations were given by Flight-Lieutenant Haslam, R.A.F.

In his final remarks, MacCurdy discussed nausea and vomiting and formulated a theory as to its physiological mechanism. Two types of sensitiveness probably exist, he suggested, one due to violent changes in the value of g, the other due to changes in the direction of g. The normal response to increase of g is tension in the extensors and rigidity of the abdominal walls. If this is ineffective, a diaphragmatic tug ensues. Dr. T. G. Maitland (Cunard Steamship Co., Ltd.) agreed that the diaphragmatic pull is important, but only as an auxiliary cause of nausea.

Dr. Maitland pointed out that the vestibule and the semi-circular canals are the chief receptors of imposed movement. They have been evolved to meet only certain modes of such movement. When they encounter movements of another order, the reflexes they evoke not only fail to maintain equilibrium, but also actually disturb it. The sensory receptors of the muscles, tendons and joints, and the skin of the supporting structures, are excited by these reflexes. These muscles give a false orientation and so vertigo is caused which is an 'emotive and hallucinatory reaction'. Vertigo, of course, may also arise from other causes.

It is not certain what part the semicircular canals, primarily receptors for rotatory movement, play in rectilinear movement, though both rotatory and rectilinear movements excite vertigo. Although evidence from experiments is conflicting, various facts suggest that rectilinear movements do affect the semi-circular canals, but not when the deviation is slight. Dr. Maitland also directed attention to the fact that the conditions of the vertigo excited by descending rectilinear movement are the reverse of those of the vertigo excited by angular rotatory movement. In the former case, the vertigo is pronounced at the inception of the movement, reaches its maximum with acceleration, diminishes with retardation, and disappears with cessation; whereas in the latter case, it is absent at the inception or acceleration of the movement, slight with retardation, and maximal with cessation.

Squadron-Leader E. D. Dickson, R.A.F., remarked that controversy has raged over the part played in flying by the vestibular apparatus, and that played by deep sensibility and eyesight in appreciating the position and movement of the aeroplane in space. In movements such as loops, spins, nose-dives, etc., the manœuvre is undoubtedly appreciated by the nerve endings in the semi-circular canals and to some extent by the otoliths, but this does not mean that consciousness is necessarily involved. In movements concerned with inclinations round a sagittal axis, such as in banking, or rising or descending, it is difficult to determine what part is played by the labyrinth and deep sensibility, and what part is played by perception of the position of the aeroplane in space. He then proceeded to discuss in detail the various evolutions practised in flying and to analyse very carefully the salient features in each. His general conclusions were: (1) the labyrinth plays no definite rôle in orientation so far as flying is concerned; (2) sight is the most important factor in informing us of our position in space; (3) in the absence of sight, deep sensibility is next in importance.

Mr. R. J. Bartlett (King's College, London) took up the position that probably one immediate physiological cause of disorientation and vertigo is insufficiency of available oxygen in the blood supply to the brain. Faulty breathing may, therefore, be a causative factor. In air and water travel, a principal cause of the faulty breathing may be the bodily reactions to the changing incidence of the pull of gravity with the rolling or pitching of boat or aeroplane. Bartlett finds that the effects of land and ocean travel can be induced in suitable subjects by vibration without any rolling, pitching or translatory movement. The subject sits in a chair attached to a box containing a motor loaded eccentrically and run at speeds from twelve to twenty revolutions per second. Changes in the frequency of the vibration and certain critical frequencies are found to be particularly effective; pneumograph records show the marked effect on the breathing of susceptible subjects. When it is difficult or impossible to keep the vibration and the breathing in harmony, discomfort is experienced.

Dr. R. S. Creed (Oxford) stated that in vertigo there must be: (1) false sensations of movement, or perhaps sometimes only of position; (2) a tendency to make compensatory movements jeopardising balance; and (3) consciousness of the falsity of the sensations, causing a feeling of uncertainty and unsafeness whence arises mental confusion and distress. The first two of these may occur alone, resulting in some degree of disorientation, and the subject may fall to the ground, but without any of the unpleasant feelings associated with the word giddiness.

In people who are particularly susceptible, vertigo accompanied even by nausea and vomiting may easily be brought about by kinæsthetic impulses or by moving visual stimuli But that the labyrinth is by far the most usual and important sense organ from which vertigo is aroused, and probably the only one concerned in sea-sickness, is now firmly established. James, Kreidl and Mygind have all commented on the immunity from sea-sickness of deaf-mutes in whom the labyrinths were deficient The experiments of Dreyfuss on guinea-pigs and of Kreidl on dogs, cats and pigeons pointed in the same direction Decerebration, decerebellation, or section of both vagi leaves sea-sickness unaffected, but removal of both labyrinths or section of both eighth nerves results in complete immunity The most likely explanation of the vomiting seems to be that it is caused by spread of excitation from the vestibular nuclei to the neighbouring medullary 'vomiting centre'.

As a result of the interest aroused in the discussion, a joint research committee of the Sections of Physiology and Psychology has been set up to investigate the conditions of vertigo and its relation to disorientation

---

Fishes of Mountain Streams

DR SUNDER LAL HORA, of the Zoological Survey of India, has for many years devoted special attention to the study of the fauna of rapidly running waters in the hill streams of India. His knowledge of this difficult and interesting branch of zoology is unrivalled No one, therefore, could be better qualified than he to undertake a detailed investigation[*] of that remarkable group of cyprinoid fishes, the Homalopteridæ These fishes, inhabitants of swiftly running mountain streams of southern Asia, have undergone a great variety of adaptive modifications induced by the peculiar environmental conditions typical of their habitat

In the first part of his report the author deals with the taxonomy of the group It is divided into 2 sub-families—the Homalopterinæ, comprising 6 genera and 31 species, and the Gastromyzoninæ which is represented by 11 genera having in all about 16 species In the Homalopterinæ 4 new species belonging to the genera *Homaloptera* and *Lepturichthys*, and 2 new varieties of *Balitora brucei* are described Among the Gastromyzoninæ no new species have been found, but in order properly to classify the existing species 5 new genera are proposed in this paper. No attempt has been made to describe in full each and every species, but wherever an amplification of the already existing description seemed to the author to be desirable the species is either redescribed or a note is inserted concerning some of its most important features

In the second part of the paper the bionomics and evolution of the Homalopteridæ are discussed at some length. The most characteristic features of its members such as flattened shape, insertion of the pectoral fins (which are used for adhesion) far forward below or even in front of the eyes, possession of a peculiar rostral groove in front of and continued along each side of the mouth, the peculiar structure of the hard and strong lower jaw, are shown to be definitely correlated with the three most important factors in the environment—strong current, high oxygen content, and nature of the food supply available. Throughout the paper attention is repeatedly directed to the 'communal convergence' that is exhibited by these fishes and to the series of characters showing parallel development in the members of the two sub-families From all the evidence which he has acquired the author believes that the Homalopteridæ are probably a polyphyletic family the members of which are derived from the Cyprinidæ and Cobitidæ and have come to resemble one another superficially under the influence of the same environmental conditions

Dr Hora is to be congratulated on having produced a paper which is not only a valuable addition to the literature on the taxonomy of the Homalopteridæ but is also of great theoretical interest.

Geological Reconnaissance by Aeroplane in Australia[*]

IN 1932 the Royal Australian Air Force made flights over many of those areas in Australia which are deemed to be worthy of investigation from the point of view of the discovery of oil Dr W. G. Woolnough, who was present as observer and geologist, has now detailed the results obtained in a report which gives valuable information regarding the function and importance of aerial work in assisting and expediting geological survey. The object was to determine the disposition of strata and especially to locate dome structures, the investigation being made partly by visual observation and partly by the study of the photographs taken from the air Much experience is required before the utmost can be achieved by these methods, and Dr Woolnough states that he scarcely began to appreciate the significance of details seen from above until he had completed one hundred hours of flying.

From July until September, a circuit of Australia was made—also a visit to Tasmania, atmospheric conditions on the whole being favourable Over Melville Island observation was hindered by a tribal fight, as part of the strategy consisted in the lighting of extensive bush fires, the smoke of which provided nuclei for the condensation of moisture and the development of clouds The orientation of the photographs and the elevation of hills and scarps above the surrounding country can be determined by noting the direction and lengths of shadows—provided the time of exposure is accurately known.

In those regions where the rocks are well exposed and where topographical forms are the direct result of the differential erosion of beds, the main tectonic features are easily seen, and examination of the photographs reveals where the detailed ground investigation, which is essential to the full elucidation of the structure should be undertaken. Most valuable is the clearness with which the true disposition and

[*] Commonwealth of Australia. Report on Aerial Survey Operations in Australia during 1932. By Dr. W. G. Woolnough (Canberra Government Printers)

continuity of strata can be made out from the bird's-eye view of country in which the ground worker is baffled at close quarters by the confusion of detail resulting from erosion, accumulations of detritus, and the presence of false dips due to local and superficial collapse of strata. The observer is warned against reading 'strike' into a banding due to the parallel alignment of superficial sand dune accumulations; furthermore, where dips are slight, it is often impossible to determine in which of the two possible directions they lie, and for this ground-levelling is required.

It was in bare featureless plains devoid of rock exposures that the most remarkable results were obtained. Sometimes it was possible to detect geological structures of great importance where the absence of outcrops presents an insurmountable obstacle to ground survey. Here a pattern can be discerned which the geologist can recognise at once as that of a geological map, and in one case the proved structure of an area with abundant outcrops was followed into adjacent lowlands the geological structure of which has hitherto remained hidden. Such pattern is due to the different appearances of soils to the 'actinic eye' of the camera. Clearly these soils have developed from the weathering of the rocks beneath them, the disposition of which they thus reveal. Pattern may be seen through thin parched grass but it is lost with a fresh luxuriant growth, and the survey must be made when the conditions are favourable.

Some success was achieved in gleaning information regarding the geology of heavily forested regions, and much may be expected from the further development of this line of attack on a type of country which is the despair of the investigator on the ground.

L. H.

University and Educational Intelligence

LONDON.—The following appointments to University readerships have recently been made: botany (Birkbeck College), Dr. F. C. Steward, since 1929 assistant lecturer in botany in the University of Leeds; epidemiology and vital statistics (London School of Hygiene and Tropical Medicine), Dr. A. B. Hill, who since 1923 has been carrying out investigations and research at the School.

The title of emeritus professor of eugenics in the University has been conferred on Prof. Karl Pearson, on his retirement from the Galton chair of eugenics at University College, and that of emeritus professor of Egyptology in the University on Sir Flinders Petrie, on his retirement from the Edwards chair of Egyptology at University College.

The following degrees have been awarded: D.Sc. to B. F. Barnes (Birkbeck College) for ten published works on botany; D.Sc. to J. C. F. Hopkins (King's College) for ten published works on plant pathology.

MR. THURKILL COOKE, a member of the General Committee of the British Association, has offered to present to the universities of England a collection of works on nautical science. The first presentation under the offer has been made to the University of London. Librarians of English universities desirous of receiving such accessions should communicate with the Assistant Librarian, British Library of Political Science, Houghton Street, W.C.2.

Science News a Century Ago

Royal Society, January 9

The portrait of the late president, Davies Gilbert, painted by Thomas Phillips, R.A., at the solicitation of several members, was, by their request, presented to the Society. A paper was read on 'The Empirical Laws of the Tides in the Port of London'. By the Rev. William Whewell, F.R.S., Trinity College, Cambridge. The author regards existing tide tables as extremely imperfect; the mathematical solutions of the problem founded on hypotheses remote from the real facts. The Earl of Tyrconnel was elected into the Society.

The Royal Medals of the Royal Society

The January issue of the *Gentleman's Magazine* in 1834 contained an excellent notice of the anniversary meeting of the Royal Society. The Duke of Sussex made a statement relative to the Royal medals placed at the disposal of the Society by His late Majesty in 1828. Mr. Chantrey, in conjunction with Sir Thomas Lawrence, was appointed to prepare a design. Either from indecision, or that procrastination for which the late president of the Royal Academy was characterised, the design was never furnished, although it was a frequent and favourite theme of conversation. After an inquiry, steps were taken, however, to redeem all the pledges made by George IV to the Royal Society. The *Gentleman's Magazine* records the awards of ten medals to the following, and the reasons: Dr. Dalton, to whom was owing the development of the atomic theory, although at the eleventh hour, it was gratifying to know that he was acknowledged as its author both at home and abroad; to Mr. Ivory, the first English philosopher who introduced to Great Britain the beautiful and refined discoveries of Laplace, Lagrange and other foreign astronomers; to Sir Humphry Davy and Dr. Wollaston in testimony of services in science; to Prof. Struve, for researches respecting double stars; and to Prof. Encke, the greatest, perhaps, of modern astronomical calculators, and the discoverer of the comet which bears his name. The Duke of Sussex alluded to Sir John Herschel as one who had terminated his European labours, and a rich harvest was to be expected as the result of his labours in the ample field of a new and unexplored heaven.

The *Mechanics' Magazine*

The issue of the *Mechanics' Magazine* for January 4, 1834 opens with a reprint of a paper by Dr. Robert Hare, then professor of chemistry in the University of Philadelphia, on a galvanic rock-blasting apparatus, in which the use of electricity is advocated for mining. This is followed by a reprint of a paper by Mr. Sang, of Edinburgh, on the relation of a machine to its model. Next there is correspondence on canal improvements, and on the performances of the steam carriages of Hancock and Maceroni, followed by a note on isometric projection and a letter from John Ericsson on his caloric engine. Of considerable interest are the notices of the activities of two societies. The Marylebone Literary and Philosophical Society, it was stated, was in a very flourishing condition and had bought 17 Edwards Street, Portman Square, where it was proposed to erect a lecture room to hold six hundred persons. Sir Anthony Carlisle, Dr. Lardner and John Phillips, the geologist, were all vice-presidents of the Society, before which many eminent men lectured. Another society flourishing then was the Brighton Literary and Scientific Society, the president of which was Mr. Ricardo. The president, so the *Mechanics' Magazine* states, had just concluded a series of lectures on railways. In the course of these lectures he had read a communication from George Stephenson in which it was said that a speed of forty miles per hour had been attained on the Liverpool and Manchester Railway and that "an engine might be constructed to run 100 miles within the hour although at that rapidity of motion the resistance of the atmosphere would be very considerable indeed".

Literary and Scientific Institutions

A correspondent contributes the following statement to the *Gentleman's Magazine* of January 1834: — The number of Literary and Scientific Societies has been greatly on the increase. The Royal Society numbers 750 members, the Antiquarian, 300, Royal Society of Literature, 271, Zoological, 2,446, Horticultural, 1,875, Royal Society of Arts, 1,000; Royal Institution, 758; Geological, 700, Linnæan, 600, Asiatic, 560, Geographical, 520, Astronomical, 320. The members constituting the London Medical, Westminster Medical, Medico-Chirurgical, Medico-Botanical, Phrenological and Entomological Societies, the College of Physicians and Surgeons, and Institution of Civil Engineers, cannot be short of 1,700 persons. Next follow the London, Russel, Western and Marylebone Institutions, whose proprietary and yearly subscribers may be estimated at 1,500. Here are in the whole 13,000 names (some it is true frequently repeated) supporting 26 Associations in London, founded for the sole purpose of promoting the interests of learning and science and diffusing useful knowledge. And, for the immediate benefit of the operative class, the Metropolis possesses a Mechanics' Institute which is said to have 1,000 members.

Investigations of Terrestrial Magnetism

About 1834 great activity prevailed in the investigation of the earth's magnetism, and magnetic observations were being made not only on land but also on exploring ships. On December 19, 1833, Commander J. C. Ross described before the Royal Society his expedition to the north magnetic pole, which he reached on June 1, 1831, and his measurement of the dip as 89° 59′. This determination was made with great care, and was as accurate as was then possible. Improvements of the magnetic instruments and the elimination of errors were being actively sought. On January 6, 1834, Mr. W. Snow Harris read before the Royal Society of Edinburgh a paper "On the Investigation of Magnetic Intensity by the Oscillations of the Horizontal Needle", in which he closely examined many real and supposed disturbing factors. He showed that light had no effect on the oscillations, but that they were susceptible to disturbance by slight air currents, and the instruments must therefore be enclosed, preferably in a vacuum. He also investigated methods of suspending magnets, the effects of changes of temperature and the determination of changes in the constants of magnets.

Darwin in Patagonia

For the greater part of 1832 and 1833, H.M.S. *Beagle*, under Capt. FitzRoy, had been on the east coast of South America, and Darwin had been able to make several expeditions inland from ports such as Buenos Aires and Monte Video. Leaving the Rio de la Plata on December 6, 1833, the vessel visited Port Desire on December 23 and then sailed for Port St. Julian farther south.

Here, on January 9, 1834, Darwin records: "Before it was dark the *Beagle* anchored in the fine spacious harbour of Port St. Julian, situated about one hundred and ten miles to the south of Port Desire. We remained here eight days. The country is nearly similar to that of Port Desire, but perhaps rather more sterile. One day a party accompanied Captain FitzRoy on a long walk round the head of the harbour. We were eleven hours without tasting any water and some of the party were quite exhausted. From the summit of a hill (since well named Thirsty Hill) a fine lake was spied, and two of the party proceeded with concerted signals to show whether it was fresh water. What was our disappointment to find a snow-white expanse of salt, crystallised in great cubes! . Although we could nowhere find, during our whole visit, a single drop of fresh water, yet some must exist; for by an odd chance I found on the surface of the salt water, near the head of the bay, a Colymbetes not quite dead, which must have lived in some not far distant pool . A good sized fly (*Tabanus*) was extremely numerous, and tormented us with its painful bite. The common horsefly, which is so troublesome in the shady lanes of England, belongs to this same genus. We here have the puzzle that so frequently occurs in the case of mosquitoes—on the blood of what animals do these insects commonly feed? The guanaco is nearly the only warm blooded quadruped, and it is found in quite inconsiderable numbers compared with the multitude of flies." ("Journal of Researches".)

Societies and Academies

LONDON

Physical Society, October 20. A. F. DUFTON: Graphic statistics. The plotting of frequency-distributions is discussed. In comparing for different populations the frequency-distributions of a particular variate, it is sometimes convenient to take one population as standard and to represent its distribution by a straight line. The method of plotting individual points described by Hazen is incorrect.

December 1. H. DENNIS TAYLOR: The image-distortion and other effects due to the glass-thickness in lens systems. The optical influence upon distortion of image, or departures from correct pictorial representation, caused by the considerable thicknesses of glass involved in the construction of high-class photographic lenses of projectors having a large angular field of view is discussed. H. CARMICHAEL: The tilted electrometer. A detailed description is given of the construction and performance of a new evacuated critically damped quick-reading quartz-fibre electrometer. The sensitivity obtainable is limited only by the Brownian motion of the fibre. The minimum potential change that can be measured (with the usual convention that the corresponding deflection of the system be not less than four times the root of mean square of the deflections of the Brownian motion), is of the order of 0 0001 v when the period (undamped) is 5 sec and 0 0005 v when the period is 1 sec The range of approximately constant sensitivity is adequate for most purposes A S RAO and K R RAO Spectra of bromine v, vi and vii The vacuum spark spectra of bromine have been investigated under different degrees of excitation in the region λ 1400 to λ 400, by means of a Siegbahn spectrograph From a careful scrutiny of the plates the lines have been assigned to the different stages of ionisation of the element With the aid of these the principal members of the spectra of bromine v, vi and vii, involving the low-lying terms, have been identified. E B MOSS An automatic photoelectric photometer A precision photoelectric photometer based on principles capable of wide application and operated from A C mains is described It is a flicker instrument, but the simple shutter is on the spindle of a synchronous motor driven from the same supply as an alternating current valve bridge This is connected to an emission type photocell, and gives a directional output which automatically moves the neutral density wedge to the position of balance, which is shown by a pointer The wedge position is controlled electrically, being mounted on a galvanometer movement devoid of mechanical control G D WEST · A mechanical wave model illustrating acoustic and electrical phenomena The model consists of a series of equal masses suspended on equal lengths of straightened watch spring from a rigid bar Through holes bored in the masses, which are equally spaced, is threaded a piece of elastic One end is fixed, and the other can move with a simple harmonic motion communicated by means of a rocker arm attached to a small motor Wave transmission along the system takes place only if the frequency falls within a certain range Very high and very low frequencies are not transmitted

DUBLIN

Royal Dublin Society, November 28 J H J POOLE Some difficulties in current views on the thermal history of the earth In a discussion of various theories of earth history it is shown that, although the conditions necessary for the truth of the cooling-earth theory may now be satisfied, it is improbable that the primitive crust would have satisfied them In consequence we must conclude that partial remelting of the original crust has occurred during some stages of geological history Some points in Holmes's convection current theory of earth history are also considered, including the condition necessary for the existence of a permanent convective layer in the earth It appears that the presence of such a layer will lead to shearing stresses in the crust, owing to the greater radioactivity of the continents and the consequent distortion of the geotherms H H POOLE and W R. G ATKINS Some measurements of the brightness of various parts of the sky by means of a rectifier photoelectric cell The measurements were made in Dublin in June and July 1933 with approximately uniform skies of various degrees of clearness, the sun's altitude being 45°–60° The minimum brightness recorded was about 0 6 metre candle per square degree for a clear blue north sky altitude 45° to 60°, and the maximum 11 8 metre candles per square degree for sky covered with light cirro stratus cloud about 12° below the sun The effect of haze, and to a greater extent of light cloud, is to (*a*) increase the brightness of all parts of the sky, (*b*) cause the brightness to increase with altitude instead of decreasing, as for a clear sky, and (*c*) increase the relative importance of regions near the sun

EDINBURGH

Royal Society, December 4 J M STAGG. The British Polar Year Expedition to Fort Rae, Canada After a brief account of the activities in 1882–83 and an explanation of the ideas leading to last year's repetition, the aims of the British Party to Rae were given The methods adopted to obtain the required information in the various fields of observation were described and some indication given of the problems to the solution of which the records brought home by the Expedition will be applied

PARIS

Academy of Sciences, November 20 (*C R*, 197, 1161-1256) PAUL DELENS Isothermal congruences. S COHN-VOSSEN The total curvature of open surfaces PAUL DIENES The deformation of sub spaces in a space with general linear connexion SIXTO RIOS The singular ensemble of a class of Taylor's series which presents gaps M FEKETE and S MARSHAK Certain conditions necessary for the regularity of a function in a point of the circle of convergence RAPHAËL SALEM Fourier's series of functions of summable square ANDRE MARCHAUD Fields of semi right lines and differential equations of the first order GEORGES BOULIGAND A problem of the theory of potential JULIUS WOLFF The conjugated harmonic function of a limited harmonic function MAURICE FRÉCHET Remarks on the communications of M Minetti concerning a space composed of holomorph functions CHR FOUSIANIS A theorem of Carathéodory and Féjer W M ELSASSER The polarisation of diffused electrons ALBERT TOUSSAINT The corrections to be applied to the aerodynamical characteristics of a supporting wing under experiment in a rectangular wind tunnel, partly guided by the walls, parallel to the spread of the wing and to the velocity of the wind PIERRE DIVE Distributions of masses producing the same potential in a common interior region JEAN CHAZY The capture of comets by the solar system MLLES RENÉE CANAVAGGIA and MARIE LOUISE FRIBOURG The constants of motion of the *G*, *K* and *M* stars L. NEEL Calculation of the [magnetic] susceptibility of nickel in the neighbourhood of the Curie point ION I AGARBICEANU The absorption of iodine vapour in the presence of foreign gases Experimental study of the absorption spectrum of iodine vapour mixed with oxygen or nitrogen, under pressures varying from 1 mm to atmospheric Existing lines were enhanced, but no new ones appeared A COUDER The use of inclined lenses as a means of producing pure astigmatism in spectrographs Suggestion for eliminating more completely the effect of the grain in the photographic emulsion PIERRE BRICOUT The photometric study of the irregularities of density of photographic plates. JEAN SAIDMAN. The technique of the measurement of the thermal radiation of the skin A description of a robust form of apparatus, capable of being carried to the bedside of a patient, and of giving more accurate results than the apparatus in current use.

Some practical applications are indicated. Véron : Rectilinear wings with uniform calorific flux René Arditti · The system cadmium sulphate, sulphuric acid, water The physical properties (solubility, density, refractive index, viscosity, electrical conductivity) of this system have been studied : results are given as curves. Mlle. Sabine Filitti The oxido-reduction potential of the system hypoxanthine, uric acid Pariselle · The influence of the strength of bases on the formation of the aluminotartaric complexes Michel Magat : The energy of dissociation of water by symmetrical vibrations and the products of this dissociation Augustin Boutaric and Marius Peyraud The capillary rise of hydrosols and of solutions of colouring matters The influence of the concentration and of electrolytes Louis Médard and Mlle Thérèse Petitpas The Raman effect of solutions of ammonium nitrate in nitric acid E Burlot · The tendency to destruction of explosives by inflammation in a vacuum. A study of mercury fulminate and lead nitride (hydrazoate) It was found that there is a limiting pressure below which the destruction of the explosive is not propagated throughout the mass of the explosive In both of these detonants there is a phase of slow combustion preceding detonation This phenomenon is easy to observe with mercury fulminate ; under special conditions described it can also be seen in lead nitride. Marcu Rotbart Some arylfatty β-oxyacetals and their products of hydrolysis. Ch Courtot and T. Y. Tung · Studies in the aryl thionium series D Ivanoff and G. Pchénitchny Syntheses with amides of the type R CH = CH. CH_2CO_2H and mixed organomagnesium derivatives Alexis Chermette : New geological observations in Bas Dahomey P Lebeau · The peranthracites and the true anthracites On the basis of work described in earlier communications, the author has proposed a classification of anthracites into true anthracites and pyroanthracites, the name peranthracites now being suggested for the latter This classification is based on the volumes of gas evolved on heating to 1,000° C Further work shows other differences between the two groups : composition of the gas evolved at 1,000° C, temperatures of inflammation, decrepitation on heating, behaviour towards chemical reagents, and electrical conductivity Peranthracites are practically conductors of electricity whilst anthracites have a very high resistivity Jacques Fromaget The Trias formations of western Tonkin P. Idrac A curious phenomenon of the solfatara of Pouzzoles Jacques Bourcart An attempt at the reconstitution of the history of the fluvial network of the Haut Atlas to the east of Marrakech P. Auger and L Leprince-Ringuet Study of the variation of the cosmic radiation between the latitudes 45° N. and 38° S The action of the earth's magnetic field on the cosmic rays should serve to discriminate between the two theories of their origin, electromagnetic or corpuscular The experiments described and summarised in a graph show that the cosmic radiation is sensible to the action of the terrestrial magnetic field, at least for distances of the order of the earth's radius J Branas and J. Dulac : The mode of action of copper mixtures : the rôle of desiccation. A. Demolon and E Bastisse : The influence of the anions on the fixing and mobilisation of phosphoric acid in soils. The hydrosol of silica and humic acids play an important part in the mobilisation of the passive forms of phosphoric acid in cultivated soils. Paul Chabanaud A new type of fish of the family of Gobideæ, *Syrrhothonus Charrieri* Description of a fish caught off the coast of Tangiers by Henri Charrier R Legendre · The presence of *Anotopterus pharao* in the stomach of *germons* Polack The anomalies of colour vision The classical trichromatic theory cannot define or place the anomaly of the Rayleigh type The author's theory, which characterises chromatic vision by two factors, the position of the luminous maximum in the spectrum and the extent of the unitonal regions, gives a precise definition and forms a continuous series with normal chromatic vision and its various anomalies G Sandor, A Bonnefoi and J J Pérez · The precipitation of the proteins by neutral salts The precipitation of natural proteins by neutral salts is not due to an isoelectric precipitability The solubility passes through a maximum at the isoelectric point *p*H 6 for the globulins and is still very high at the isoelectric point *p*H 4 8 for the albumins.

Industrial Recruitment and Educational Policy

THE valuable section in the final report of the Balfour Committee on Industry and Trade, which considered education as a factor in industrial and commercial efficiency, emphasised the urgent need for each great industry to make its own educational needs the subject of thorough and systematic examination, "particularly because the changing forms of organisation and mechanical equipment and the subdivision of occupations which characterise some of the more important industries are continually modifying the nature and extent of their educational needs, and these changed needs can only be fully known to those actually engaged in industry"

The five years which have elapsed since this report was presented in March 1929 have subtracted nothing from the cogency of its argument On the contrary, the growing intensity of international competition supplies a strong insistent force, which was previously lacking, impelling those engaged in industry and commerce to consider how they should improve the efficiency of their personnel as well as of themselves It has become clear, too, that those personal qualities, on which we have relied in the past far more than on specialised knowledge, are by themselves inadequate to meet modern demands for leadership and must be supplemented by greater knowledge and a wider outlook Finally, the chaotic conditions to which the economy drive of the last two years have reduced education in Great Britain are causing misgivings in the minds of the most stubborn regarding the capacity of the next generation—whether in rank and file or in leadership—to maintain our higher standard of living in the face of modern competition

Suggestions for co-operation between industry and educational authorities have frequently been put forward, and were indeed worked out in detail in the report of the Malcolm Committee, which recommended that the Board of Education should establish a small special body representative of the views of employers, workers, local education authorities and teachers to undertake national negotiations In the report on Trade Schools on the Continent, which was issued in 1932, two inspectors of the Board of Education directed attention to the danger to our industrial efficiency which is presented by the growing vertical immobility of labour, as well as to the necessity of organising our institutions for technical education less in response to a demand from below and more in response to the actual requirements of industry as seen by its leaders In his recent book on "Education for Industry and Commerce in England", Mr. A Abbott makes an even more emphatic plea for a complete review of our methods of industrial recruitment, training and promotion He urges that each industrial organisation should consider carefully first what types and grades of workers it needs and in what numbers and secondly, from what types and grades of schools these should be drawn

The relation between industrial recruitment and educational policy and development has been overshadowed by the unemployment question, but the growing extent of juvenile unemployment is once again focusing attention on this problem If only as a means of checking continuous recruitment into occupations where juvenile employment is already disastrously high, steps must be taken to afford the youth of the country suitable training for those industries which can offer them a reasonable prospect of employment and advancement in their chosen work, they must not be left to enter those which are merely exploiting wholesale their defenceless situation

As a first step to this end, it is obvious that each industry must be able to formulate its own requirements and to do so continuously, so that with the selection of recruits there is associated a definite plan of training and promotion In spite of the discussions which have centred round training for management, and the care which is now taken in some industries in the training of recruits, whether drawn from the universities, from technical schools or from secondary and elementary schools, the bearing of the developments in post-primary education recommended under the Hadow scheme on industrial recruitment and promotion is as yet scarcely realised by industry The net result of educational selection at the age of eleven years for post-primary or other schools with a leaving age above fourteen, will be that the members of the selected group will greatly outstrip those of the unselected group in competition for the more responsible and attractive posts of industry Its responsible officers will to an increasing extent come from a group of individuals picked out at an early age for prolonged education, and its rank and file will come from the larger group of individuals not so selected

It is accordingly desirable not merely that industry shall formulate its requirements as to the training to be given before and after recruitment, the standard and type of education desirable in its recruits, whether for the rank and file or for the more responsible positions It is equally important that the whole methods of recruitment should be reviewed and modified or replaced by better methods desirable Recruiting policy must take account of the changed conditions of education and not be content to follow blindly the methods of generations ago, regardless of their suitability or unsuitability

There is little doubt that a re-examination of recruitment policy would speedily result in enlisting a considerably higher proportion of students who had received a good previous education in part-time classes of the technical schools, and thus tend to raise the general standard of the rank and file of industry The quantitative aspect of recruitment is, however, equally important Each industry should be able to give a reasonably accurate estimate of the number of recruits it expects to require during a period of years from each class of school—those with students at a leaving age of fourteen years. the post-primary schools and the technical schools giving a full-time education up to eighteen and those coming from the universities or technical colleges of university rank

Industrial planning on this scale is long overdue The mischief which has been done by extravagant statements regarding the demand for chemists or other classes of scientific workers, for example, causing an influx of students to such courses in numbers far exceeding the capacity of the industry to absorb them, is difficult to assess but has been widespread in the last decade Similar or even more vicious conditions are to be found among every category of student from the elementary school upwards Even at the present time such industrial planning cannot be dismissed as impracticable or visionary Such books as Prof G C Allen's "Industrial Organisation in Great Britain" have demonstrated the imperative need for industry to face the facts, if any, if our lost prosperity is to be recovered or indeed our standard of life maintained

One incidental result of such an estimate would be to bring out into clear relief those industries which are making little use of men with a wide and thorough scientific training, or relying entirely on relatively untrained sources for the recruitment of their rank and file Lack of efficiency, because those responsible for the direction of an industry did not possess sufficient knowledge and training to make use of the facts now available for them, would be speedily correlated with its true cause, and the community would be in a strong position to refuse to allow palliatives in place of remedial measures.

On this ground alone some opposition may be expected to any proposals for the planning of a policy of technical education and industrial recruitment. The advantages which such a policy offers, however, are too solid to be thwarted by mere reactionary or prejudiced views There is first the imperative necessity of securing for the service of industry competent workmen and skilled foremen, who possess the ability to meet the demands of this age for a new kind of skill based on considerable intelligence, a sound general education, a willingness to develop fresh interests and a capacity for adaptation to fresh tasks Secondly, there is the advantage of securing the staffing of industry generally with university graduates, or men with wide scientific knowledge and training, not merely for the purpose of research but also for securing that full advantage is taken, in every sphere, of the new tools which science is constantly forging, whether for new production, increased efficiency, or the safeguarding of life and health

We here touch on perhaps the most fundamental need of all It is probably true to-day that most, though not all, industries have a research organisation in one form or another which is adequate to their present needs, and there are indeed a number of industries in which new knowledge is being gained more rapidly than it is utilised There are, moreover, many branches of industry in which there is no real hope of applying the new knowledge gained by the various research organisations until the qualifications of the men at the top have been improved

This is largely a matter of training for management, of seeing that those recruits for industry who are destined ultimately for its management or administrative staff should have had a broad general education on which they have built a first-rate scientific education Apart from the absolute necessity of adequate scientific knowledge for sound and prompt decisions as to whether and how a new piece of knowledge can be utilised, whether its utilisation is likely to be permanently profitable, its reaction on other production and development, whether a difficulty encountered in works practice should be solved on the spot or more wisely referred to a research organisation or department, the significant check to the vertical mobility of labour makes the old haphazard habit of recruitment for management inadequate We can no longer expect that recruits of the requisite calibre will continue to work their way up from the bottom, or that those who do raise themselves to some extent will possess the wide knowledge and breadth of vision required of those in administrative or managerial posts.

Technical knowledge is, of course, only one of the factors required in the higher management of industry It is equally important that a policy of industrial recruitment should take full account of the various institutions, such as the Department of Business Administration at the London School of Economics, of Industrial Administration at the University of Manchester, or the Institute of Industrial Administration, which are specifically directed towards training for management The training given in those courses must be regarded rather as fitting the students to take fuller advantage of their industrial experience, and to qualify themselves ultimately for the more efficient discharge of administrative duties The courses are not a substitute for wide technical and scientific training They are rather complementary, and require planning in close relation to industrial requirements and opportunities, if mobility of staff on the technical side is not also to be discouraged

The demand which a policy of industrial recruitment makes for co-operation between industry and educational authorities is obvious It is less apparent, however, that its achievement demands a widespread interest in the community, and particularly a general conviction that technical education is a most powerful instrument for maintaining and increasing technical efficiency Unless public opinion regards technical education not as an attempt to train well-disposed and ambitious individuals for higher posts but as a definite effort to train an industrial army, officers and rank and file alike, which by its *moral* and technique will safeguard and strengthen the economic life of the State, there is unlikely to be forthcoming the support which will undoubtedly be necessary if the opposition of such backward industries as the cotton industry to a planned policy is to be overcome.

There are at any rate signs that a considered policy is within the bounds of possibility. The alarming position of juvenile unemployment in Lancashire has already focused attention on the exploitation of juvenile labour in the cotton trade in the absence of a recruiting policy, and has led the Lancashire authorities to initiate their own plan for raising the school age and working the Hadow scheme A definite policy with regard to the recruitment of laboratory assistants for scientific laboratories, who in the past have provided an unhappy example of a blind alley education, has already been adopted by some industrial firms and promises to mitigate or avoid this difficulty. In addition, there is a growing tendency for professional organisations of scientific workers, such as the Institute of Chemistry, to interest themselves in technical education, whether in post-graduate classes, or in the training for higher positions in evening or part-time classes of those already engaged in industry

The association of scientific workers is an essential element in the elaboration of an adequate policy The task of educating public opinion as to the bearing of technical education on industrial efficiency, whether among the leaders or the rank and file, must fall largely on them On their researches and investigations the continuous development of technical education depends In their personal capacities, whether in industrial or educational posts, they must make important contributions to the detailed elaboration of policy There are few fields in which larger demands for public service are made on the profession of science than in just this field of technical education, upon which the industrial future of Great Britain now so closely depends

The solution of our problems of education for industry and commerce, and the elaboration of adequate and harmonious relations in regard to recruitment between industry and education, depend largely upon the capacity of the organised scientific industrial and commercial professions to exert deliberately and continuously the same liberalising influence on standards of education as the so-called liberal professions have exerted less consciously and actively in past centuries Technical education from one point of view is the training of industrial personnel, and this is an essential factor in the permanent recovery of industrial prosperity From another point of view it is the use of applied science as a means of higher education , and to demonstrate our ability to use applied science as an agent of education as previous generations used the classics may well prove to be one of our greatest achievements in this century.

African Folk-Lore

Myths and Legends of the Bantu. By Dr. Alice Werner. Pp. 335+31 plates (London, Bombay and Sydney . George G. Harrap and Co , Ltd., 1933.) 15*s*. net

DR. WERNER is best known in the field of African philology, for her knowledge of Bantu tongues is probably unique, and beyond doubt these acquirements have greatly facilitated her researches into the mythology of the people dealt with in this work. Such a patient and discerning investigation must therefore command great respect

Folk tales have, through the ages and all over the world, always had an attraction for mankind, otherwise they could not have survived, but it is only during the last fifty years or so that they have received attention from analytical minds. Thanks to the researches of E B Tylor, Sir James Frazer and others, the study of the legendary lore of primitive folk has been accorded a definite place in anthropological science, and its importance is now fully recognised As the author remarks in her preface, it now seems incredible that Moffat in 1842 could state that a description of the manners and customs of the Bechuana would be "neither very instructive or edifying", and another distinguished missionary referred to the "absurd and ridiculous fictions" of the tribe. This attitude persisted in East Africa to much more recent times, but information dealing with beliefs, customs and arts has of late years poured in from all quarters

We have in the work before us a *corpus* of mythological material the wealth of which is staggering, and it is only owing to its painstaking division into classes by the author, that the student can obtain a grip of the essentials.

As will be well known to most, the term Bantu has little racial significance, for it refers solely to a language group of people. That is to say, over a vast extent of Africa we find masses of people, often of diverse physical characteristics, all speaking languages referable to the same original tongue. The persistent uniformity of structure in the various branches of Bantu speech over such a vast area is a remarkable phenomenon, when we consider that it was adopted by many racial groups which must have had languages of their own, and of which there is now but little trace.

Besides the language relationship, there is another remarkable fact, namely, that those to whom a Bantu language has become the mother tongue have, generally speaking, the same religious beliefs. All are monotheists, although the idea of a high god is often not clearly distinguished from the sun, the sky and even the first ancestor of the tribe The basic fact in their religion is, however, the belief in the power and influence of the dead, whence it follows that they believe in survival after death, for they are convinced of the intervention of the spirits of the departed in the affairs of the living. This fact is relevant to the origin and survival of their mythology, for if this belief had not existed, much of it could never have been born. The folk tales give an invaluable insight into the workings of this belief, for it would appear that although they rarely see the dead in the flesh, the spirits reappear in the guise of birds, sometimes as snakes and even as children The spirits of the dead sometimes exercise a moral influence and there are several cases where a murderer is detected by the intervention of a spirit personified in the shape of a bird They may inflict punishment, too, if neglected, or as a judgment on some undiscovered lapse in tribal law.

The unfettered power of metemphycosis which is believed to be possessed by the spirits of the dead has played a great part in the development of the folk-lore of Africa, and for that reason the connexion between the religion of these people and their mythology should not be lost sight of, even if it does not explain all.

The belief in heroes and demi-gods flourishes among the Bantu-speaking peoples, quite in accordance with the legendary myths of the classics and of the Norse lands The lives of the famous Ryang'-ombe, Liongo and others may be quoted. The birth of the hero often occurs in unusual circumstances and he skips adolescence, acquiring mature strength with miraculous rapidity, his precocity is such that any attempt to kill him is at once detected. Around some of these figures quite a *saga* of legends has accreted, and although many of the happenings are impossible, there may be a basis of historical fact. Belief in these characters persists among the people of Africa even to-day.

Next comes the folk-lore, in which animals play a great part. Included in this group of legends are the stories in which the special feature is a swallowing monster, which is eventually killed by a hero and then all is well, for its victims emerge unharmed We have here reminiscences of the 'Giant Killer' and Jonah of whale fame so familiar to all of us.

In the animal group we have, too, a multitude of stories which fall into what may be called the "Brer rabbit" class, made famous throughout the civilised world by "Uncle Remus" Needless to say, in Africa the rabbit is really the hare, for there are no rabbits. The general motif of the stories is that a small beast, physically weak but blessed with cunning, defeats slower witted but stronger beasts such as the lion, elephant, etc. According to local taste or for some recondite reason, the place of the hare is sometimes assumed by the chameleon—which, by the way, is blamed for the introduction of death—the jackal, and as for the tortoise, he comes into a group of stories of his own It is the "old man Tarrypin" of the Uncle Remus collection

The occurrence of the triumph of small defenceless creatures which is such a feature of these stories, excites curiosity The author considers that it is stressed owing to a natural sympathy for the 'under dog', others are inclined to emphasise the African tendency to exalt low cunning Both reasons may have an influence

The detection of similarities in mythical stories from parts of the world remote from each other has for long given rise to astonishment and has often led to controversy Diffusion throughout the Bantu-speaking language group has obviously occurred, but so far as can be ascertained, the myths do not appear to afford much argument for their dispersion from that much-favoured centre—Egypt It is true that, in her final chapter, the author identifies a limited number of legendary stories as being, for example, similar to such well-known folk-tales as Cinderella, to stories from Assam, the Buddhist Jatakas, even the medieval "Gesta Romanorum", and so on. Truly folk tales may be said to have travelled even more extensively than ancient beads.

It is, of course, impossible here to do more than refer to a few of the most striking examples of legendary lore which are set forth in this volume While expressing appreciation of this work, may one say that it is impossible to avoid a regret that the learned writer did not give us her views regarding the genesis of the mythical material, and also discuss the mental processes which have produced such an amazing mass of legendary matter. The work is well produced and is illustrated by a series of excellent photographs of an apposite character. C. W. H.

Science and Railways

A British Railway behind the Scenes: a Study in the Science of Industry By J. W Williamson. Pp. x+213+25 plates (London. Ernest Benn, Ltd, 1933) 5s net

THIS book is a study in the application of science to industry, as exemplified in the organisation, operation and development of the London Midland and Scottish Railway. The author discusses the design, building and repair of locomotives and rolling stock, the construction and maintenance of the permanent way, signalling, operation and control of traffic, 'rationalisation' and costing, and scientific research There is also a brief chapter on the many interests of the undertaking which are ancillary to its main business of transport

The London Midland and Scottish Railway was incorporated ten years ago, under the Railways Act of 1921, through the merging of eight constituent and twenty-seven subsidiary companies with an aggregate authorised capital of approximately £424,000,000. Interesting details are given which indicate the remarkable range and diversity of this gigantic corporation's activities For example, we are told that in 1932, transport facilities were provided for 407½ million passengers, and 117 million tons of freight As an employer, the undertaking rivals the Post Office, with a staff of approximately 225,000 persons In addition to rail transport, it controls and operates docks, steamships, canals, motor and horse-drawn vehicles It also incorporates the largest hotel business in Europe, whilst staff duties range from engineering to weed-killing, and from scientific research to the provision of dance bands

Few industrial trends are so full of promise as the adoption of scientific research and the scientific method by modern business corporations In 1930 the L M S Railway, inspired and encouraged by Sir Josiah Stamp, appointed a research committee with Sir Harold Hartley as director of research The activities of the committee are closely linked to the company's costing system, which discloses the desirability of making investigations. Research is thereupon initiated, the primary object of which is to effect economies in working, whilst also aiming at greater efficiency and safety throughout the system. Sir Harold Hartley is quoted as saying that "the outlay has already been repaid by results achieved, and we look forward with confidence to the cumulative effect of continuous scientific study and research". There is no central research laboratory, since it is considered better policy to take full advantage of facilities provided by the research organisations of the Department of Scientific and Industrial Research, the universities and industrial research associations The undertaking has chemical laboratories of its own at Derby, Crewe, Horwich and St Rollox, and specialised laboratories dealing with paint, textiles, metallurgy and the mechanical testing of materials

It would manifestly be impossible to give more than a bare outline of the company's far-reaching activities within the limits of this book The outline provided, however, is one that conveys to the reader a satisfactory impression of the undertaking as a whole and as a going concern Considerable difficulty must have been experienced by the author in selecting his material, and he is to be congratulated upon the successful manner in which he has accomplished this task The book is agreeably written, it is competently planned and the balance of the chapters is well maintained

Although ostensibly limited to an exposition of how this great railway functions, the book may also be regarded as a contribution to the study of industrial administration It is not that there is anything strikingly novel about the administrative methods discussed. There is already an extensive literature on railways in general, and a literature at least equally voluminous dealing with subjects such as simplification, standardisation, processing, planning and costing In particular a vast amount of theory, hypothesis and (may we whisper it?) 'hot air' has been evolved in recent years to which the name 'rationalisation' has been applied

It is well for the student of industry, who is increasingly compelled to follow scientific method in his studies, to leave this somewhat rarified atmosphere from time to time and turn to the contemplation of theory in process of successful application to practical business affairs "The great benefit which a scientific education bestows," said T. H Huxley, "is dependent upon the extent to which the mind of the student is brought into immediate contact with facts." Immediate contact may be supplemented to advantage—at least where industrial processes are concerned—with the indirect contact afforded by books such as that under review. Therein lies their chief value to all students of industrial organisation and management

Oil and its Uses

Earth Oil By Dr Gustav Egloff (A Century of Progress Series) Pp xi+158 (Baltimore, Md · The Williams and Wilkins Co., London. Baillière, Tindall and Cox, 1933) *5s 6d*

THE word oil is a household one to-day, since the ingenuity of man has found a myriad uses for it As 'petrol' in England, 'gasoline' in America, 'essence' in France, it serves as the source of power to propel cars for work and for play, while as a social influence it may be claimed to have altered the habits of nations It behoves us, therefore, to know something of oil, perhaps of its history and the methods of locating it, but certainly about the methods of mining or drilling for it, its storage, transportation and refining, including those modern developments of the oil technologist and oil chemist such as cracking and hydrogenation Even the subject of oil resources has its interest, whilst it is of great economic and strategic importance It is to fulfil such requests that this little book has been written The author, Dr Gustav Egloff, who is a deservedly popular leader among petroleum technologists, is able with his pen, aided by numerous illustrations, to portray for us almost in moving picture form the oil story, and well he does it

It is certain that the uses for oil will increase and that it is almost an ideal material for the internal combustion engine It is a strange reflection on international economics that those countries which lack oil are seeking to replace it by substitutes and protect these by taxation The world's use of oil to-day is far below the producing capacity of the actual wells, of which 330,000 are producing in the United States alone at an average rate of seven barrels per well per day Vast reserves both known and undiscovered are left underground, further, the newer methods of production and refining all give far higher yields of product from a ton of crude oil There is thus no fear of an oil shortage, but every encouragement to go on to make more use of it

The past summer has seen the holding of the first International Conference of Petroleum Technologists at South Kensington, at which all matters pertaining to oil were discussed among experts Its outstanding success indicates the certainty of further progress in every direction

One aspect still baffles us, namely, the origin of oil It is a subject for the geologist to tackle in addition to his task of locating oil—this last a subject in which enormous strides have been taken as a result of the co-operation of the physicist Crude oil sometimes has much, at others little, sulphur and the same applies to nitrogen Different crudes vary in almost every respect—some are nearly all gasoline, as in California, some are practically solids No one theory of petroleum production is in any way satisfactory The earth is generous to mankind perhaps oil is one of her greatest gifts and those lands which have it are specially favoured

The book is issued in connexion with the Chicago Century of Progress Exhibition. few would dispute the claim of the oil industry to be in the forefront of such progress E F A.

Short Reviews

Lehrbuch der okologischen Pflanzengeographie Von Prof Dr Eug Warming und Prof. Dr P Graebner Vierte Auflage Lieferung 5 (Schlusslieferung) Pp viii+961–1157 (Berlin Gebrüder Borntraeger, 1933) 18 gold marks.

THE publication of the fifth part completes the fourth edition of Warming and Graebner's "Lehrbuch der okologischen Pflanzengeographie" The sclerophyllous vegetation of districts with winter-rain, subxerophilous grass formations, and deserts are here considered A final chapter deals with the struggle between plant communities Title-page, preface, contents and index are also included

The new edition is a most important work of reference and gives an excellent summary of world vegetation and of the causal or correlated physical and biotic factors. It is written in relatively simple language without undue stress on technical terms. Most of the illustrations are adequate and some are excellently reproduced and very instructive, but no attempt is made to illustrate the distribution of the communities or 'formations' by maps. The most unfortunate feature is the bibliography Only an appendix to the literature listed in the third edition is given, and to trace most of the papers quoted, reference to this earlier edition is necessary So many important post-War English and American books and papers have been overlooked that a false impression is given that ecological and phytogeographical studies are not being pursued with any intensity outside Central Europe

The death of Prof. Graebner, while this last part of the "Lehrbuch" was in press, is recorded with deep regret. W. B. T.

The Book of Chemical Discovery. By Leonard A. Coles. Pp. 288+31 plates. (London, Bombay and Sydney: George G Harrap and Co, Ltd., 1933) 7*s*. 6*d*. net.

EVERY book that makes the achievements of science and its problems known to a wider circle of the public is to be welcomed. Mr Coles gives a judicious blend of the past, the present and the future—wisely in our opinion, for he who would understand the future must venerate the past. The story of the dawn of chemistry, of the age of alchemy, is far more interesting than that of the lives of the contemporary kings and queens and their favourites, if only we could persuade the public to read the former instead of the latter. Even the daily Press now takes notice of atoms, molecules and electrons with the transmutation of the elements a fact, the wheel of progress has taken a full turn.

Mr Coles is happy in his treatment of the industrial section, though it might perhaps be a little more up to date, even if the latest wonders of synthetic production are a little more difficult to explain His final chapter on problems will leave his readers thoughtful, conscious of the progress which is being made and of how much remains to be done.

The book is far more accurate than many similar efforts, and as it wisely confines its ambit, it is able to cover the subject very completely · it is an ideal school prize or present. E. F. A

Handbuch der landwirtschaftlichen Bakteriologie Von Prof. Dr F. Lohnis Zweite, neu bearbeitete Auflage Band 1, Teil 1. *Futtermittelbakteriologie* Von Prof Dr F. Lohnis. Pp. 105 10 50 gold marks Band 2, Teil 1· *Dungerbakteriologie* Von Prof Dr. G Ruschmann. Pp 158 15 gold marks (Berlin Gebruder Borntraeger, 1933)

THE old "Handbuch" of the late Prof Lohnis has been enlarged, these parts being the first of the second edition to appear The price may seem high for paper covers, but the fund of information supplied is very rich, so that the work will be of great value on library shelves individual workers will appreciate the new edition, though few may be able to buy it as a whole

Without slighting the text, it may be said that the extensive running bibliography—which frequently occupies more than half of the page—will be the feature most sought after The plan of Band 1, Teil 1, includes discussions on bacteriological aspects of the preparation and self-heating of hay; silage; decomposition processes, and their control, in various types of fodder; technique of examination; and an especially interesting section on the rôle of micro-organisms in animal digestion. The plan of the larger part ("Farmyard Manure") is comparable. The work is generally up to date, though no description of the A.I.V. ensilage process is given.

The Outlook of Science: Modern Materialism. By R. L. Worrall. Pp. v+203. (London: John Bale, Sons and Danielsson, Ltd., 1933.) 8*s*. 6*d*. net.

IN this useful and provocative work, the author denounces the idealistic tendencies of modern science and pleads for a revival of philosophical materialism. It is true that the extensive mathematisation of science has carried away from reality some of our most prominent men of science. A series of well-chosen quotations from leading physicists and biologists are taken as a basis by the author for a searching criticism of their idealistic point of view. The sympathy one may feel for the author's critical endeavours, however, can scarcely be lavished on his constructive conclusions Inspired by the crude materialism of the Russian thinkers, the author gives as a keynote of his philosophy the very controversial assertion that mind is derived from matter. The elaboration of a tempered dualism would have saved him from many pitfalls T. G.

The Handbook to the Roman Wall· a Guide to Tourists traversing the Barrier of the Lower Isthmus By the late Dr. J Collingwood Bruce. Pp x+221+1 plate Ninth edition (Newcastle-on-Tyne: Andrew Reid and Co, Ltd; London: Longmans, Green and Co, Ltd, 1933) 3*s* 6*d* net

A FAMOUS handbook, written seventy years ago and now in its ninth edition, would call for little comment, if it were not that it is claimed by the editor, Mr R. G. Collingwood, than whom no one is more competent to pronounce an opinion, that it is now the most complete account of the Wall that has appeared since 1867 Much matter of antiquarian interest that would now be considered irrelevant has been excised, the information has been brought fully up to date, and a bibliography appended The utility of the handbook has been enhanced while its attractiveness as an account of the Wall is unimpaired

Earth-Lore Geology without Jargon. By Prof. S J Shand. Pp viii+134+4 plates (London. Thomas Murby and Co., 1933) 5*s* net.

IN his latest book Prof Shand outlines the major facts of geology and touches lightly on some of its unsolved problems The subjects dealt with include. earth sculpture, the sea floor, the age of the earth, the problem of the mountains, and drifting continents.

The book appears to be intended for those of the thinking public who may wish to know what geology is and what geologists are thinking about to-day. The use of 'jargon' has been very largely avoided and simple explanations have been furnished for such technical terms as are used.

"Earth Lore" should appeal not only to the wider public for which it seems to have been expressly written, but also to students of geology who require an up-to-date conspectus of their own subject.

Sheffield Steel

THE intimate association of Sheffield with the steel industry is probably even better known and appreciated than the proverbial relationship between coals and Newcastle. In the former case the industry has developed practically from its very birth within this city to its present unshakable and unique position in the industrial world, and although steel-making in England is now rather more decentralised than was formerly the case, Sheffield still holds pride of place in respect of both historical associations and present-day importance

The rise of Sheffield as a metallurgical centre may be attributed in part to certain natural advantages and to the gradually accumulated skill of generations of craftsmen of the city, but pre-eminently it must be ascribed to the important contributions made to steel metallurgy by such men as Huntsman, Bessemer and Sorby. It was here that Benjamin Huntsman, in the years between 1730 and 1740, conceived the idea of melting the carburised bars of Swedish wrought iron in crucibles, and persevered with his experiments until the practical difficulties associated with this novel procedure were surmounted. The Huntsman method of melting and casting proved a great advance on the methods then in use for the production of shear steel by hammering the bars of carburised wrought iron, and gave a much more uniform and coherent product From this time onwards to the middle of the nineteenth century, the crucible process of steel-making developed rapidly in Sheffield, and the tool steel produced acquired that reputation for quality and reliability which has characterised all Sheffield products down to the present day.

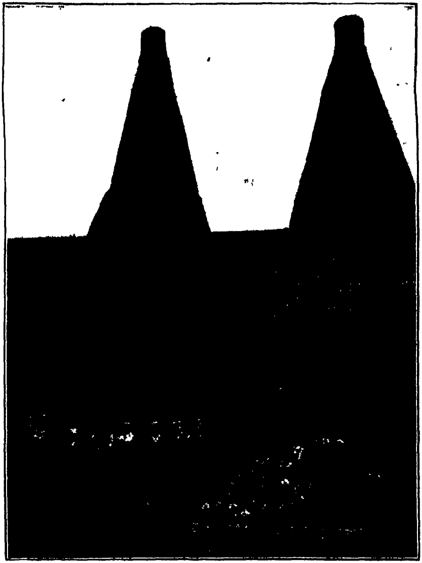

FIG. 1. Huntsman's original works and furnaces Reproduced by courtesy of Sir Robert Hadfield.

Some time after the rise of the Huntsman process, it was found possible to combine carburisation and fusion into one operation by melting together a mixture of Swedish wrought iron and charcoal, and, eventually, attempts were made to substitute English wrought iron. The latter procedure was eventually made commercially practicable by the introduction of manganese into steel-making, due to Heath, who in 1839 took out a patent covering the addition to cast steel of manganese in the form of a carbide, prepared by roasting manganese dioxide with carbonaceous matter.

Then followed the Bessemer process for the treatment of molten pig iron by blowing air through it. This process, which was put on a commercial footing in Sheffield, made it possible to produce structural steel cheaply and in reasonable quantity. Later came the development of the open-hearth regenerative furnaces by the brothers Siemens, working in conjunction with Pierre Martin The Siemens-Martin method made possible the huge outputs from individual furnaces which have characterised more recent years, and also led the way to the development of the long list of alloy steels now in use for a variety of engineering purposes

Again, it was a citizen of Sheffield, Henry Clifton Sorby, who devised the microscopic method of examining the structure of metals and laid the foundations of the science of metallography and the technique of heat treatment Sorby first described the various constituents and structures met with in steel—the pearly laminæ, surrounded either by areas of soft iron or by membranes of a much harder constituent—and thus enabled rational and coherent ideas to be substituted gradually for the atmosphere of mystery and secrecy which had surrounded the operations of steel-making.

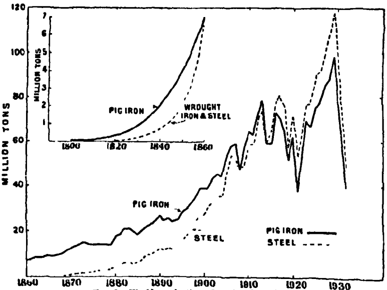

FIG 2. World production of steel and pig iron

Two books recently published* place on record much that is of absorbing interest in connexion with the development of the steel industry. Both authors are able to give personal experiences of the steel-making days of more than half a century ago, yet both are still actively interested in modern technique and production methods

Sir Robert Hadfield's address of welcome to the members of the Iron and Steel Institute who visited Sheffield for the autumn meeting of the Institute is an attractively prepared brochure containing an unique collection of nearly a hundred photographs of past and present metallurgists, and should be of considerable interest and value to those connected with the Sheffield industry or with the University of Sheffield A vivid sketch is given of the rise of metallurgical industry, with particular reference to the City of Sheffield, together with a miscellany of historical references and personal reminiscences. Throughout the book stress is laid on our great debt of gratitude to the workers of the past, both inventors and craftsmen, upon whose labours the structure of modern steel metallurgy has been erected

An interesting account is given of the details of Huntsman's method of manufacturing crucible steel, as witnessed by the French metallurgist, Gabriel Jars, and described by him in his "Voyages Metallurgiques", published in 1774 The historic photograph here reproduced (Fig 1), of Huntsman's original works and furnaces, gains in interest by reason of the fact that it was taken by the late Prof J O. Arnold, of the University of Sheffield The following section surveys the rapid expansion which occurred between 1750 and 1850, owing to the development of the Bessemer process, the Siemens-Martin process, and the basic Bessemer and open-hearth processes The rise and development of alloy steels are discussed, with particular reference to the Hadfield inventions of manganese and silicon steels Mention is also made of the newer types of heat and corrosion resisting steels, but surprisingly little is said on the subject of the high duty structural steels for automobile and aircraft purposes, which to-day constitute a considerable proportion of the total output of alloy steels An interesting diagram, here reproduced (Fig 2), shows the total world's output of steel and pig iron from 1800 down to 1932.

Succeeding chapters deal with the growth of metallography and heat treatment, the associations of Sheffield with national defence and the manufacture of armaments, and the importance of industrial research Probably the most interesting section of Sir Robert Hadfield's address is that surveying the development of metallurgical education in Sheffield, and the work of the Faculty of Metallurgy in the University under the successive professors, Greenwood, Arnold, Desch and Andrew. Reference is made to the research department for the cold working of steel, and to the recent project for the establishment of a degree course in foundry work

Some interesting details are given of the formation of the Iron and Steel Institute in 1869, and of the important part played by the Institute in encouraging research and disseminating knowledge in ferrous metallurgy, and we can heartily commend Sir Robert's advice to all interested in the iron and steel industry to become associated

---

* "Address of Welcome to the Iron and Steel Institute visiting the East Hecla Works of Messrs Hadfields, Ltd , on September 14, 1933 " Pp. viii+112. (London Chapman and Hall, Ltd.) 5s

"Steel-Makers." By Harry Brearley Pp. xiii+156. (London, New York and Toronto· Longmans, Green and Co., Ltd , 1933) 5s net with this body The address closes on a note of encouragement to the younger generation of metallurgists, for whom the future holds in store a wealth of opportunity

Mr Harry Brearley's book makes exhilarating reading His main thesis concerns the value of the judgment and vision of the workman—of the art as opposed to the science of steel-making. This idea is developed with the aid of some pertinent thrusts at the too highly scientific metallographer or chemist, who is apt to use a language which only the initiated can understand and to become unintelligible to those who dutifully read his reports "There are complaints that what should be, or might be, a clearing house for difficulties is apt to degenerate into a priestcraft able to obscure a difficulty if not explain it "

Mr Brearley has some hard things to say on the subject of the teaching of metallurgy and the comparative neglect of the process side of steel metallurgy "And as what the schools call metallurgy turns out to be almost exclusively metallography, there is little wonder that the graduate student comes into the works with notions about the importance of this or that which are sadly out of balance . As a supplement metallography is excellent as a superseder of the older forms of observation and deduction it may not be so excellent—it may be misleading What a man sees through a microscope is more of less, and his vision has been known to be thereby so limited that he misses what he is looking for, which has been apparent at the first glance to the man whose eye is informed by experience " This leads to views on technical education which are definitely constructive, and a very interesting and attractive suggestion is put forward for the teaching of steel metallurgy under industrial conditions

Mr Brearley's book is in part autobiographical, dealing with the author's early days as a cellar-lad in a tool-steel furnace—an occupation he entered at the age of eleven or twelve—with the intimate details of the crucible process as practised in Sheffield in the 'eighties, and with his admiration for the skilled steel-melters with whom he came in contact "The goodness of the craftsman is in his bones and beats with his blood The same unruffled confidence, and modesty too, which unfolds itself in men like Faraday unfolds also in humbler workmen , and whilst in them uncouth expression might be mistaken and misunderstood, there are such men whose opinion, muttered in their sleep, is valuable beyond the calculated views of others Amongst even steel-melters there are 'mute, inglorious Miltons' " L B H

The Asiatic Society of Bengal

By DR L L FERMOR, O B E

AS the Asiatic Society of Bengal is arranging to celebrate on January 15 the one hundred and fiftieth anniversary of its foundation, a short account of its activities will be of interest

The founder of the Society, Sir William Jones, a Puisne Judge of the Supreme Court at Fort William in Bengal, arrived in Calcutta in 1783 Sir William Jones, who was a distinguished scholar and linguist, soon noticed the want of an organised association as a drawback to progress, and with the co-operation of his friends held a meeting on January 15, 1784, at which thirty gentlemen representing the *élite* of the European community in Calcutta were present Sir William Jones delivered a "Discourse on the Institution of a Society for enquiring into the History, civil and natural, the Antiquities, Arts, Sciences, and Literature of Asia" ; and as a result of this address it was resolved to establish a society under the name of the "Asiatick Society" The name adopted for the Society at the inaugural meeting was borne on the records until the close of the fourth decade of the nineteenth century

In 1829, soon after the foundation—by Henry Thomas Colebrook, a former president of the Asiatic Society—of the Royal Asiatic Society of Great Britain and Ireland in London, and the affiliation of the Literary Society of Bombay with that institution, a letter was received from the Royal Asiatic Society offering to the Asiatic Society in Calcutta the privilege of affiliation, and in this letter the Asiatic Society was for the first time designated as the "Asiatic Society of Bengal" The Society did not accept the affiliation or the change of title, but as the parent of all the Asiatic Societies extant it fitly retained its original name of *The* Asiatic Society In 1832, also, when Mr. James Prinsep sought the sanction of the Society to use its name for the journal he was then about to start, the resolution used the words "Asiatic Society" only , but the editor found it convenient to add a local designation and, in 1843, when the journal became the property of the Society, the new name of Asiatic Society of Bengal had already become familiar and it was formally introduced into the code of by-laws published in 1851 This title has been used continuously since

This detail concerning title has been deemed necessary because of the confusion that sometimes arises between the titles Asiatic Society of Bengal and Royal Asiatic Society of Great Britain and Ireland, and because it is not always realised that the Asiatic Society of Bengal is the parent and older body

In his inaugural dissertation, Sir William Jones expounded the definition of the aims of the Society contained in the title of his address and his words have been paraphrased into: "The bounds of its investigations will be the geographical limits of Asia, and within these limits its enquiries will be extended to whatever is performed by Man or produced by Nature", and this sentence now serves as the motto of the Society.

At the second meeting of the Society it was decided to invite Warren Hastings, then Governor-General of India, to accept the office of president of the Society Hastings declined the honour on the grounds of his inability to devote sufficient attention to the work of the Society and for other reasons, and requested the permission of the Society to yield his pretensions to the gentleman whose genius planned the institution Following this suggestion, Sir William Jones was elected the first president and held office until his demise in 1794

The institution thus planned and founded has had a continuous existence down to the present and is still in active being In 1884 the Society celebrated the centenary of its foundation and published a centenary review volume, in which is a full account of the past century's work of the Society This volume contains first (Part I) a history of the Society, from which the foregoing details have been taken. Then comes in Part II a review of the literary activities of the Society, classified under archæology, history, literature, etc. From this section the reader will learn the outstanding part played by the Asiatic Society in the deciphering of inscriptions on stone and metal, (coins and pillars), and in texts on palm leaf and paper, and in the discovery of the clues to ancient scripts, with resultant contributions to the history of ancient India In this section outstanding names are Sir William Jones himself, Henry Thomas Colebrook (the founder of the Royal Asiatic Society), Horace Hayman Wilson (of the Medical Service of the East India Company, Assay Master of the Calcutta Mint and finally Boden professor of Sanskrit at Oxford), and James Prinsep (who succeeded Wilson as Assay Master)

Part III of the centenary volume summarises the researches in science published by the Society, classified under mathematical and physical sciences, including meteorology, geology, zoology, botany, geography, ethnology and chemistry Amongst researches to which reference may be made are the Venerable Archdeacon Pratt's views on the importance of allowing for Himalayan attraction in determining the curvature of the arc of the meridian in Hindustan, Capt J T Newbold's researches on the geology of Southern India, work on the correlation and classification of the Peninsular formations of India, particularly the researches of Thomas Oldham and W. T. Blanford, the work of Hugh Falconer and Proby Cautley and others upon the rich vertebrate fossil fauna of the Siwalik Hills, Brian Hodgson's studies of the bird and mammalian fauna of Nepal, Sikhim and Tibet, and the work of the "Indian Linnaeus", William Roxburgh, on the plants of the East A rich field was tilled by a number of workers on the ethnology of the numerous tribes of India.

In the early days of the Society, the East India Company, the predecessor of the Crown in India, had no organised scientific services, and the scope for such a society as the Asiatic Society in collecting, describing and classifying the natural history objects of India, particularly in the fields of geology, zoology, botany and ethnology was enormous; and the *Asiatic Researches*, the first publication of the Society, and the volumes of the *Journal of the Asiatic Society of Bengal*, contain a great number of papers on aspects of the natural history of India These activities led to the accumulation of a large quantity of specimens, in consequence of which the Asiatic Society was compelled to found its own museum Ultimately, the increasing volume of material proved too great a tax on the resources of the Society, and negotiations were opened with the Government of India, which terminated in the establishment of the present Indian Museum, in accordance with Article XVII of 1866 The collections of the Asiatic Society of Bengal were then entrusted to the Indian Museum, which is administered by a board of trustees on which the Asiatic Society of Bengal was, and still is, represented These collections were incorporated with the collections belonging to Government or made by Government departments, such as the Geological Survey of India, founded in 1851

The formation of several Government scientific services, such as the Geological Survey of India, the Indian Meteorological Department, and the Botanical Survey of India, the Zoological Survey of India, and the Agricultural Research Institute at Poona, each department with its own journal or journals, now diverts to the respective publications a large number of papers that would formerly have been presented to the Asiatic Society of Bengal In addition, the formation of specialist scientific societies, such as the Indian Chemical Society, the Indian Physical Society and the Mining and Geological Institute of India, affords an outlet for the papers of non-official workers in science, many of which in the past would have been offered to the Asiatic Society of Bengal. The consequence is that the number of papers in science offered to the Asiatic Society of Bengal has fallen during the fifty years now ending much below the figures of the past

The Society has not, however, lost its importance to science Apart from its historical rôle of parent and sponsor directly or indirectly of many of the scientific societies and Government scientific departments in India, the Society now undertakes the important duty of organising the Indian Science Congress Association, a body that plays in India a part analogous to that of the British Association in England, meeting annually in January at different centres in India The Society not only acts as organiser and office to the Indian Science Congress Association but also publishes the annual volume of *Proceedings* of the Congress meetings

In respect of science, therefore, the Asiatic Society of Bengal now plays the rôle of an 'elder body'. There is a general feeling that with the formation in India of an increasing number of specialist and local societies, and the resultant increasing tendency of sciences to work in isolation from one another, that a greater measure of co-ordination is required than is afforded by the annual meetings of the Indian Science Congress, the question of forming an Indian Academy of Sciences is consequently under discussion. One possible solution would be that the Asiatic Society of Bengal should occupy a position analogous to that of the Institute of France and become the parent body for not only an Indian Academy of Sciences, but also for an Indian Academy of Letters to represent the other side of the present activities of the Asiatic Society of Bengal and other groups of men of letters in India. Such a development, with perhaps a reversion of the title of the Society to "Asiatic Society" without the words "of Bengal", so as to remove the provincial sound, would seem to be the simplest solution to the problem and one that would well celebrate the hundred and fiftieth anniversary of the Asiatic Society, should this seem appropriate to the scientific workers of India as a whole. Such a development would also have the great advantage of preserving the liaison that still exists between science and letters in India.

Economics of Nutrition

THE Council of the British Medical Association, having realised that the adequate nutrition of the population is a matter of national importance, appointed a committee in April 1933 "to determine the minimum weekly expenditure on foodstuffs which must be incurred by families of varying size, if health and working capacity are to be maintained, and to construct specimen diets". The report of the committee was printed as a supplement to the *British Medical Journal* of November 25, 1933, which has now been reprinted.

The feature of the pamphlet is a series of sixteen carefully compiled diets suitable in quantity and variety for a single adult man, for children of various ages and families of different sizes. The quantities of the foodstuffs are calculated in accordance with the physiological standards and 'man value' of the families from Cathcart and Murray's figures. A family consisting of a man, a woman, and four children of the ages thirteen, ten, seven and four years, according to this standard has a man value of 4·63.

Stress is laid upon the kind of protein, whether it is of animal origin (first class), or of vegetable origin (second class). The infant's diet of milk consists of animal protein only, and it is advised that the change from the infant's to the adult diet be gradual, with the maintenance of a high proportion of animal protein, and be not completed until the child is three to five years of age. The amount of animal protein is maintained at a high level (60–75 per cent of the total protein) at any rate until school age is past, as shown in the specimen diets, and may be continued at this level so long as the child is growing. Unfortunately, the introduction of animal protein adds to the cost of the diet and is not always practicable. It is recommended that the supply of protein for the child be from cheese, fish and minced meat. We may refer to diet No. 4 proposed for a child of one to two years. It is based upon a minimum of 1 pint of milk daily, which is looked upon as the maximum expenditure which is likely to be possible on this article of food. The weekly quantities are: milk 7 pints, meat ¼ lb., fish ¼ lb.; butter ⅛ lb., flour 1 lb., oatmeal ¼ lb., sugar ⅛ lb., potatoes 1 lb.; ½ lb. each of cabbage, turnips, carrots and tinned tomatoes. In this diet the proportion of animal protein is 71 per cent of the total protein and the calorie value is 1006, the child of this age corresponding to a man value of 0·3.

Similar diets with proper first-class protein for older children of three to six years are given in Nos. 5 and 6. In diets Nos. 7 and 8, for children of six to ten years, the milk is reduced to ½ pint daily.

Diet No. 1 is an example of the bare ration without variety for an adult man and costs 58·25 pence weekly. With variety the cost is increased to 70·5 pence weekly. Diets 9–16 are family diets with one or more children of different ages, and the man cost of these diets is 76·1–66·5 pence weekly. The costs have been calculated from a special scale of prices ascertained by the British Medical Association. Another scale of lower prices gives those prevailing in Stockton.

So far as the diets are concerned, the variety and quantities are extraordinarily well chosen and could be universally adopted. We would earnestly recommend all schools and institutions to use these standards of quantities and regard them as the *minimum*, increasing the quantities of milk, meat, fish and egg if funds permit. Children would thus be given a fair start in life. There is at present a tendency in school diets to restrict the supply of first class protein to a level inconsistent with the demands of growth between the ages of fourteen and eighteen years.

A considerable proportion of the specimen diets consists of dairy produce, vegetables and fruits. The minerals of the diet are thus amply provided. The supply of vitamins, especially of A and D, and C is regarded as sufficient from the quantities of milk, butter, eggs, cheese, liver, fish and vegetables. It is pointed out that whole cereals, beans, peas and lentils are the source of vitamin B, but some of the diets do not contain any of these articles of food, and if included the weekly total of such foods is very small. No stress is laid upon the advantage of wholemeal bread in preference to white bread or flour, for the supply of the vitamin B group, and in respect of this vitamin the diets cannot be regarded as satisfactory.

A main criticism will always be the costs of the diets, which naturally vary greatly according to season and locality. It is not often that a palatable egg can be purchased for a penny. Cheese at 6d. per lb. is not everywhere procurable, and minced meat at 6d. per lb. is not likely to be of good quality, but consist mostly of gristle and fat. Still, the diets show that for a weekly expenditure of 5*s*.–6*s*. 6*d*., a man can procure a well-balanced diet.

The calorie value of these diets is based upon the daily consumption of an adult man, which has been assessed at 3000. Diet as consumed is not the same as diet as purchased since allowance has to be made for waste, such as bone in meat and fish, outer leaves of vegetables, etc. This waste is commonly reckoned at 10 per cent. The calorie values of the diets is given as 3400 as purchased. This gives a figure of 3060 as consumed. This does not thus vary appreciably from that adopted by the Ministry of Health following a report on dietary investigations of which an account was given in NATURE of June 13, 1931 (vol. 127, page 897). There is no doubt, however, that many families can exist upon a smaller calorie intake, down to 2500 calories, depending upon their manual work.

The allowance of first-class protein of 50 gm. a day appears to be a higher allowance than that of the Ministry of Health. The minimum quantity has been assessed at 37 gm. a day. The Army ration in peace time contains 62·7 gm. of first class protein. There can be no serious objection to taking the mean figure of 50 gm. a day, especially when a family including children is taken into consideration.

August Weismann, 1834-1914

THE name of August Weismann, the famous professor of zoology in the University of Freiburg-im-Breisgau, the centenary of whose birth falls on January 17, will always be remembered as that of one who exercised a profound influence on the progress of biological doctrine and speculation. As a teacher of zoology Weismann achieved a far-reaching reputation; and by the students who worked under his direction, among whom, it may be remembered, was the late Prof. Gilbert Bourne of Oxford, his instruction was estimated at the highest value. But it was as an investigator and explorer of the methods of evolution that his influence was most widely felt, especially perhaps in Great Britain.

It was Weismann who first detected the true significance in the development of the insect wing of the rudimentary larval structures noticed by previous observers. His work on the embryology of the Diptera, and especially of *Corethra*, led him to the recognition of the origin of the appendages of the adult insect in hypodermic downgrowths to which he gave the name of *Imaginalscheiben* (imaginal discs or folds). Linked with this came his discovery of the remarkable phenomenon of histolysis, which he supposed to be of more general occurrence than later observations have shown to be the case. The importance of Weismann's work in this department was early recognised by Darwin, who contributed a prefatory notice to the "Studies in the Theory of Descent". This was the book through which, owing to the good offices of Prof. Meldola, Weismann's biological theories were chiefly brought to the notice of men of science in Great Britain. To the "Studies" may be attributed the impulse which started Prof. E. B. Poulton on many of those lines of investigation which have led in his hands to such fruitful results.

The outstanding claim of Weismann to the attention of biologists, however, was his bold challenging of the supposed effect of Lamarckian factors in heredity. This view, at the time of its publication, was no less than revolutionary. The opposition that it aroused, at first strong and sustained, has never completely died down; at the present day, however, the votaries of Lamarckism are comparatively few in number. To this result the developments of Mendelism have contributed in no small degree, but the first effective attack on the transmission of somatic modifications was delivered by Weismann. His elaborate scheme of 'biophors', 'determinants' and 'ids' has not stood the test of later investigation; there is no doubt, however, that his postulate of 'determinants' foreshadows in many respects the present-day conception of 'genes'. Moreover, in his theory of intra-germinal selection, by which he sought to reconcile the old antagonism of preformation and epigenesis, he may be said to have anticipated in some measure the modern doctrine of the interaction of genetic factors in ontogeny.

Weismann was led in course of time to modify to some extent the somewhat exaggerated view that he took of the inaccessibility of the germ-plasm; but the distinction now generally drawn between the genotype and the phenotype is evidence of the virtual stability of the position first definitely established by him. It would be interesting to know, were it possible, what his attitude would be in face of the developments that have followed on Mendel's discovery of the segregation of the gametes.

Weismann, with his tall figure and pleasant demeanour, was a striking and attractive personality. He was not averse from discussing the relations between science and philosophy, though he was fully aware of the limitations that exist on both sides. His general position may be briefly summarised in his own words, translated by Meldola as follows: "The mechanical conception of Nature very well admits of being united with a teleological conception of the Universe."

Obituary

SIR FREDERIC NATHAN, K B E

COLONEL SIR FREDERIC LEWIS NATHAN died on December 10 at the age of seventy-two years As a young artillery officer who had passed through the advanced class of the Ordnance College, Capt F L Nathan, as he was then, was detailed to take part in the experimental work of Abel, Dewar and Kellner, who were bringing out at Woolwich the smokeless propellant cordite He was thus at the birth of that explosive, to the improvement and manufacture of which he was to devote his energies between 1892 and 1909 at the Royal Gunpowder Factory, Waltham Abbey, as Assistant- and then as Superintendent During these years it can fairly be said that a new technique was introduced into the manufacture of explosives. The methods of Waltham Abbey were adopted by the then numerous private firms making explosives, while later the propellant factories erected during the War embodied the features of Waltham Abbey practice

The improvements made during this time included a reorganisation of the work of the factory, to which Sir Frederic devoted the energy of a logical and business mind, the invention and introduction of new processes of manufacture of cordite and its ingredients, the study of danger precautions in manufacture on which he became an authority, and the recognition of the importance of investigative work

Having raised the Royal Gunpowder Factory to the highest pitch of efficiency, Sir Frederic retired from the Army to apply his methods to the Nobel factory at Ardeer, of which he was works manager from 1909 until 1914, and in March 1915 he was appointed adviser to the Admiralty on cordite supply when he was given the task of designing and laying out the Royal Naval Cordite Factory at Holton Heath Here, on an open area, unencumbered by ancient water-ways and existing buildings as at Waltham Abbey, he had free scope to erect a magnificent propellant factory such as would embody his experience of process and study of precautions for safety, and in which there was orderly progress from raw to finished material This having been completed and put into operation, Sir Frederic became Director of Propellant Supplies under Lord Moulton

After the War Sir Frederic concerned himself for a time with the safety of explosives in coal-mines, and as a member of the Department of Scientific and Industrial Research he gave his attention to the possibilities of home-produced alcohol as a motor fuel, and later to fuel research, for which he was the Department's Intelligence Officer up to the date of his death In this capacity he applied himself to the extraction of what was relevant in the literature and to the best methods of indexing it He was also chairman of the Association of Special Libraries and Information Bureaux (A S L I.B), editor of a *British Power and Fuel Bulletin* issued by the World Power Conference, and projected at the time of his death the publication of an *International Power and Fuel Bulletin* in three languages, indexed according to the decimal classification of the Institut International de Bibliographie

Among other activities should be mentioned Sir Frederic's interest in the training of the chemical engineer, this being the title of his presidential address to the Institution of Chemical Engineers, of which he was one of the founders and twice president He was also Commandant of the Jewish Lads' Brigade for twenty-one years. He was knighted in 1906 and became K B E in 1918 Lady Nathan and three sons survive him. His third son was killed in action on June 14, 1917

Those who came into contact with Sir Frederic Nathan could not fail to recognise his high ideals, his great industry and his methodical mind, those who had the good fortune to work with him found in him an inspiration and constant support in the appreciation and furtherance of their scientific work ROBERT ROBERTSON

MR A E P WEIGALL

WE regret to record the death on January 2 at the age of fifty-three years of Mr Arthur Edward Pearse Weigall Mr Weigall was the son of Major A A D Weigall He matriculated as a member of the University of Oxford from New College in 1900, but after a brief residence joined Sir Flinders Petrie's staff for archæological exploration at Abydos in Egypt In 1905 he was appointed Inspector-General of Antiquities under the Egyptian Government, a post which he held until 1914 His archæological work was recognised by his appointment as officer of the orders of the Red Eagle (Germany), Franz Josef (Austria), and the Medjidieh (Egypt)

Weigall was a prolific and versatile writer, his work ranging from the record of archæological investigation to the purely imaginative effort of novel writing. His gifts were perhaps most happily displayed in the imaginative interpretation of archæological and historical data as in his "Life of Akhnaton, Pharaoh of Egypt" (1910) and "Life of Cleopatra, Queen of Egypt" (1914) Among his numerous archæological and historical works may be mentioned —"Abydos" (sections of) Parts 1 and 2 (1902 and 1904), "Report on the Antiquities of Lower Nubia" (1907) , "Catalogue of Weights and Balances in the Cairo Museum" (1908) , "A Guide to the Antiquities of Upper Egypt" (1910) ; "The Treasury of Ancient Egypt" (1911) , "Tutankhamen and other Essays" (1923) ; "A History of the Pharaohs" (1925–26) and with A H. Gardiner "Topographical Catalogue of the Private Tombs of Thebes" (1913) He was also the author of a book of travel, "Travels in the Upper Egyptian Deserts" (1909).

News and Views

The Loch Ness "Mystery"

SINCE a note appeared in NATURE regarding the alleged "monster" of Loch Ness (Dec. 16, 1933, p. 921) evidence has accumulated, on one hand, to warn the credulous against the suppositions of unskilled observers, and on the other to point to the identity of the creature which has caused so much commotion in the daily newspapers In the first place, the writer of these notes has examined, through the kindness of the Associated Press, the original negative, said to be a direct photograph of the Loch Ness "monster", from which prints appeared in various newspapers about December 6 and 7. Regarding this photograph, it is not necessary to say more than that the object appears not to have been photographed at the distance stated, 200 yards, and that in the writer's opinion the object represents no animal known to science In the second place, the "spoor" of the animal, about which fantastic tales were spread, has, according to the *Morning Post*, led the authorities in the British Museum (Natural History) to conclusions decidedly unfavourable to some of the expectations previously aroused No support was found in this evidence of the 'monstrousness' of the monster

As to the other side of the story , in the *Scotsman* of January 1, appeared a sketch made by an observer, and on January 6, the *Aberdeen Press and Journal* published a sketch made by a final year veterinary student who saw the creature on land by the Loch side, by the light of the moon and of his motor cycle lamp, who, somewhat boldly it would seem, upon his knowledge of natural history and prehistoric animals, stated his opinion that it was "a cross between a seal and a plesiosaurus" But the sketch and the description of the beast and its movements are more reliable than the identification Without analysing these in detail, for they are wonderfully accurate considering the physical light and the mental atmosphere which surrounded the creature, one can have little doubt that the object figured in the *Scotsman* and seen and sketched by Mr A Grant in the early morning of January 5, was a large grey seal. The species occurs not infrequently in the Moray Firth, whence it probably comes from its nearest breeding grounds in the Orkney Islands , it is the common species of the western isles of Scotland

Exhibition of British Art

THE winter exhibition at the Royal Academy is devoted this year to British art and it was opened to the public on January 6. The first president of the Academy, Sir Joshua Reynolds, whose dignified statue by Mr Alfred Drury, R A , stands in the courtyard before the entrance to the Royal Academy at Burlington House, once said . "Variety reanimates the attention, which is apt to languish under continual sameness". There is certainly no lack of variety in this exhibition Sir Joshua was one of the earliest to make scientific experiments as to the effect of light and atmosphere upon the permanence of pigments. Since his day the chemist and physicist have given much attention to this subject, with the result that modern paintings, as well as showing great brilliance, undoubtedly possess that lasting quality which is so desirable. No. 568 in Gallery IX is a striking example, and if the rainbow is a little too solid-looking, it at least has the merit of having the colours in the right order. The greater permanence under suitable conditions of water colours, which of course do not suffer from the darkening of varnishes or media used in oil paintings, is a feature of the exhibition, and attention may be directed in this respect to No 801, by Rowlandson, and especially to the beautiful work of Cotman, Turner and others In the Architectural Room may be seen a case containing thirty-five watches all made in England between the years 1583 and 1751

Symbolism in Art

AT the Friday evening discourse delivered at the Royal Institution on November 17, the audience had the unusual, but instructive, experience of hearing, in Sir Herbert Baker's account of "Symbolism in Art", a distinguished practitioner of this form of expression in architecture on his principles, not from the æsthetic, but from the historico-scientific point of view The discourse is now available in printed form The interpretation of symbols, which is an element of no little importance in the study of art and the history of religions, suffers in a large number of instances from the drawback that it must be a matter of inference, and sometimes merely guesswork Sir Herbert, in demonstrating to his audience the ideas which inspired, for example, the choice of motifs and subjects in the design of arms for the provinces of India used in the decoration of the new Delhi, showed the methods of the symbolising mind, first seeking the characteristic quality or incident pertinent to its subject, then giving it concrete form—thus, for example, selecting for the arms of the United Provinces the meeting of the sacred rivers at Allahabad, the bow of Rama, whose capital was at Oudh, and the fishes, the emblem of world power of the old Nawabs of Lucknow. Should events confirm Sir Herbert's diagnosis of the present trend of development in art towards symbolism, as the place of representational art is taken by mechanical means of reproduction, clearly the historical study of these principles and methods of symbolic art, of which he deplored the lack in the early part of his discourse, will demand increasing attention

SIR HERBERT BAKER treated his subject-matter under two heads, touching first on early historical phases of symbolism and then describing attempts which he and collaborating artists have made to embody in the medium of art some facts of human experience As already indicated, it is the personal experience upon which the latter part of the discourse was based, which gave weight to the view of symbolism taken in the introductory historical sketch. Here Sir Herbert took the lightning flash and the thunderbolt as the first expression by early man in his 'rude art' of the symbolism of divine power. The gods depicted by man held the symbol of the thunderbolt first as a weapon, later as a baton or sceptre of authority. In that form, Sir Herbert pointed out, it is a widespread symbol in all primitive art. It occurs among Minoans, Greeks, Romans, the Hittites, in Mesopotamia, Central Asia, India and Mexico. The bolt was traced, with the addition of the wings of Jove, as it developed into the trident of Poseidon and Britannia and the lily of France. Two interesting examples of misinterpretation were quoted, which are not without a moral for those who practise interpretation of symbols: first, Napoleon mistook the *fleur de-lys* of Clovis for bees and changed the *fleur de lys* in his own arms and those of Paris to representations of that insect; secondly, the Belgians took the flower on the French soldiers' uniform for representations of the frog and christened the French *crapauds* accordingly.

Sounding the Ionosphere

Prof. E. V. Appleton showed in our columns in 1931 the importance of determining the variation, with frequency, of the equivalent path traversed by wireless signals returned from the ionosphere, since such determinations measure the maximum density of ionisation in the regions sounded. The letter from Mr. R. Naismith which we publish in our correspondence columns this week describes work which he carried out in May 1933. We understand that publication was deferred in accordance with an agreement between British and German workers that none of the results of radio work within the programme of the Second International Polar Year should be published until after the end of that year. The letter directs attention to the need for a rapid and more or less completely automatic method for recording the relation between the radio frequency of the pulse signals used and the equivalent path traversed by them in their double journey to and from the ionosphere, at nearly vertical incidence. At the time when the work described was carried out, there were available several methods for the continuous automatic recording of equivalent path against time of day, for a single frequency, but not for the more difficult problem of recording path against frequency.

The radio staff at the U.S. Bureau of Standards has been working on the same problem, and at the annual convention of the Institute of Radio Engineers at Chicago on June 27, 1933, Mr. T. R. Gilliland (*Bur. Stds. Jour. Research*, Oct. 1933) described an automatic recording system giving records of the required type over the frequency range of 2500–4400 kc./s., the frequency being varied at the uniform rate of 200 kc./s. per minute so that the full range was covered in about ten minutes. The closeness of dates between the American and British work is illustrated by the fact that Mr. Gilliland showed a record for April 22, 1933, while Mr. Naismith shows one for June 6 and informs us that his first record was taken on May 20. The means of investigation thus made available is clearly a very powerful one, and geophysicists will look forward to the results of the further developments promised from the Bureau of Standards and the National Physical Laboratory.

Yorkshire Scientific Magazines

The publication of the December issue of the *Naturalist*, the monthly journal of the Yorkshire Naturalists' Union, completes a hundred years of the regular publication of this scientific magazine. The *Naturalist* originally appeared under the title of the *Field Naturalist* as an octavo monthly of 48 pages in January 1833, under the editorship of Mr. James Rennie. It ran for fourteen issues and then appeared under the title of the *Naturalist*, edited by Mr. Neville Wood, of Doncaster. In 1851 the second series of the *Naturalist* commenced under the editorship of Beverley R. Morris, and later the Rev. F. O. Morris, author of the well-known "History of British Birds", the third series, edited by C. P. Hobkirk, appeared from Huddersfield in 1864. The fourth series of this magazine were edited by Joseph Wainwright and appeared from Huddersfield under the changed title of the *Yorkshire Naturalists' Recorder*, but the fifth series, in August 1865, reverted to the present title, the *Naturalist* (Sheppard, "Yorkshire's Contribution to Scientific Literature", *Naturalist*, 1915). The fifth series, edited by Messrs. C. P. Hobkirk and G. T. Porritt, was issued at Pontefract, but later transferred to Leeds under the editorship of W. D. Roebuck and W. Eagle Clark, in 1884. In 1889, W. Eagle Clark, leaving for Edinburgh Museum, vacated his editorial post and Roebuck continued to be editor until 1912, assisted by E. R. Wade in 1892. In 1902 the *Naturalist* was issued from Hull under the editorship of T. Sheppard, assisted by Dr. T. W. Woodward. Mr. Sheppard relinquished the editorship in 1932. He was succeeded in 1933 by Dr. W. E. Pearsall and W. R. Grist as editors, when the *Naturalist* once more was issued from Leeds.

Few counties have such an interesting record of scientific journalism as Yorkshire, and the *Naturalist* has watched many contemporary magazines rise and fall in its century. The *Bradford Scientific Journal* and the *Halifax Naturalist* were contemporary magazines. The *Circular* appeared as a scientific monthly in Halifax, 1866, while the *Practical Naturalist* commenced in Bradford in 1883 and was continued at Ilkely. The *Naturalists' World* was another of Ilkely's scientific monthlies and in 1879 the *Young Naturalist* appeared from Hartlepool and Huddersfield, becoming the *British Naturalist* in 1891, but ceasing issue in 1894. From 1882 until 1883, the *Naturalists' Monthly* was issued from Bradford and in 1892, the *Naturalists' Journal* commenced, later becoming *Nature Study* and being issued from Huddersfield, where it ceased publication in 1905. The *New Nature Study* commenced at Huddersfield in 1912 but was short lived. The Malton Field Naturalists' Society issued a monthly journal, *Naturalists' Notes*, at the end of last century, while the *Natural History Journal* was published at York from 1877 until 1898 A contemporary, the *Naturalist*, but with no connexion with the present journal of that name, appeared monthly in York in 1834, mainly for school nature students

Conference of Educational Associations

THE twenty-second annual Conference of Educational Associations was held at University College, London, on January 1–8 Dr George Dyson, of Winchester College, in his presidential address on "Education for Life", said that though there is a great and growing interest in music and the arts, it is still true that the writing of poems, the making of pictures, the modelling of statues, the playing of sonatas, the composition of songs, are regarded as frills Our education is a system of mental education, training only a fraction of human faculty and character He recommended a system of differentiated secondary schools, one type being frankly a workshop

THE Great Hall was crowded on January 4 for a discussion on "The Failure of Modern Science to develop an Adequate Cultural Background to Life" Dr W W Vaughan presided and the discussion was opened by Prof Julian Huxley, who said that the defects of scientific education are over specialisation, the failure to link science to other studies and over-emphasis on physics and chemistry, as against biology and related subjects There is a tendency to devote too much time to practical work He considers that science should be studied as an integral part of history and that more attention should be given to applied science, the aims of science teaching being a coherent general outlook in which scientific ideas are integrated, and the inculcation of the scientific method in human affairs Sir Arnold Wilson's contribution to the discussion showed that he favours the teaching of science in elementary schools, in which he thinks there should be great development, and he stressed the ethical aspect of science teaching and its hope of bringing inspiration, strength and inward peace to mankind and stability to civilisation The subsequent discussion elicited several useful suggestions, one being that young and rapidly developing branches of science might be considered from the viewpoint of their educational value. Several speakers referred to the importance of personal influences, the use of leisure, and emotional life and experience as contributing to 'cultural background'

Association of British Zoologists

THE annual meeting of the Association of British Zoologists was held in the rooms of the Zoological Society in Regent's Park on January 6 On previous occasions the Association has been interested in the provision of revision classes in biology at the universities for school teachers. Dr F A Dixey reported the work which the Council of the Association has done in the past year on this subject Classes are now provided at several universities and have been well attended In view of the expansion in the teaching of biology in schools which is now taking place, the subject is recognised as important, and the Council was asked to continue its activities. Mrs. M D Brindley, opened a discussion on the possibility of providing some means by which information concerning the British fauna could be made more easily and rapidly accessible The preservation of the fauna among the rapid and widespread changes which are bound to occur in a thickly populated country is difficult, but it is a task in which zoologists must always be interested Changes in the fauna are often of importance to the community At present a very large amount of information on the natural history of the fauna has been collected but much of it is scattered through many, often obscure, journals

PROF D M S WATSON gave his views of the scope of the teaching which should be carried on in a university department of zoology In order that the student may be able to deal later with the biological problems which will be the subject of his investigations, his teaching should be broad and should be concerned as much with the natural history and physiology of animals as with their structure Prof Watson gave an account of the way in which these views have been expressed in the design of the buildings which have recently been built for his department at University College. Some problems of zoological technique were also discussed Prof H G. Cannon gave a lecture on the technique of making drawings for the illustration of zoological papers. It is hoped that the Council will be able to publish his lecture

Ninth International Congress of Pure and Applied Chemistry

SPAIN will act as host for the ninth International Congress of Pure and Applied Chemistry, which will be held in Madrid on April 5 11, 1934, under the patronage of H E the President of the Spanish Republic and of the Spanish Government. The object of the Congress, which was to have been held in 1932, is to promote the progress of pure and applied chemistry, and to strengthen relations between chemists throughout the world The president of the bureau of the Congress is Prof Obdulio Fernández, and the general secretary is Prof Enrique Moles, the address of the organising committee's office is San Bernardo 49 (P O Box 8043), Madrid (8) Membership is of three categories · honorary members, comprising the committees of honour and of patronage, and the official delegates of the Spanish Government and of the governments of other countries, supporting members, who pay the minimum amount of 300 pesetas; and active members, who pay a fee of 75 pesetas (about £1 17*s* 6*d*) Members' ladies pay 25 pesetas only, but they will not be entitled, as members are, to receive publications *in extenso*, the daily bulletin, summaries of communications, or the report of proceedings Membership is open to societies, institutions, etc , connected with any branch of pure or applied chemistry, and to individuals interested therein Applications for membership should be made to the general secretary before February 15, 1934, and should be accompanied by a remittance made payable to the treasurer. Pamphlets containing the rules of the Congress and other information can be obtained in England from Mr S E Carr, The Chemical Society, Burlington House, Piccadilly, London, W 1.

GROUPS and sections of the ninth International Congress of Pure and Applied Chemistry have been organised as follows: (1) Physical and Theoretical Chemistry, pure (electrochemistry, photochemistry), applied (colloid chemistry, rubber, tanning and leather materials, electrometallurgy), (2) Inorganic Chemistry, pure, applied (glass, ceramics, cement, mineralogy, metallurgy), (3) Organic Chemistry, pure, applied (colouring materials, explosives, sugars, starches, cellulose, paper, fats, oils, soaps, colours, paints, varnishes); (4) Biological Chemistry, pure, applied (medical and pharmaceutical chemistry, fermentation industries), (5) Analytical Chemistry, pure, applied, (6) Agricultural Chemistry, (7) History and Teaching of Chemistry, Economics and Chemical Legislation. Papers may be in the language with which the author is familiar, but the organising committee suggests the use of such languages as will avoid typographical difficulties when rendered into Latin type Summaries must be given in English, French, German, Italian or Spanish Scientific communications intended for the Congress should be forwarded by February 5, 1934 The Congress will comprise general lectures, lectures, followed by discussions, in the various groups, and original communications. The general lectures will deal with mineral chemistry, organic chemistry and biochemistry

Metric System in China and Turkey

ON December 1 of last year, the Chinese Government issued a notice to the effect that the metric system of weights and measures would be introduced into the Customs service on February 1 According to the Shanghai correspondent of the *Times*, the metric system has been applied in the collection of the salt tax since January 1 On the same date, Turkey adopted metric weights and measures, and that system is now obligatory throughout Turkish dominions in Europe and Asia. Thus Turkey, until recently one of the most backward of the European powers, has come into line with the majority of modern States, and no doubt her commerce and industry will benefit from the consequent simplification Several attempts have, of course, been made to introduce decimal weights, measures and coinage into Great Britain, but the most that has been achieved is the legalisation of the use of metric weights and measures, and the adoption of such terms as 'metric ton'. It would seem that the fuller use of the metric system in Great Britain, like the introduction of the 24-hour clock, is unduly delayed by the prevalent inertia of unscientific public opinion

Non-Reflecting Windows

NON-REFLECTING windows are beginning to be used for shops. The reflectionless window is a British invention It is made of a concave sheet of glass so constructed that the light from all sources incident on it is reflected to two black boards arranged one at the top and one at the bottom of the glass The eye of the observer looking at the glass from in front is completely unaffected by any of the reflected light, the result being that it is very difficult to believe that there is any glass between the objects displayed and the observer The prospective buyer therefore views the goods more clearly and is not distracted by images It is also claimed that the reflectionless window effects an appreciable saving in the cost of artificiable lighting, since every lamp in use is able to give its full illuminating value and has not to compete with the disturbing effects of outside rays reflected by the window The new window is applicable to all shops whether new or old, and for maintenance it costs no more than an ordinary plate-glass window An illustrated description of the reflectionless window is given in the *Illuminating Engineer* of January, 1934

Expedition to East Africa

AN important expedition for archæological and geological exploration of the Northern Frontier Province of Kenya Colony left England on January 4 Its purpose is to carry out a topographical and geological survey in the neighbourhood of Lake Rudolph in the great Rift Valley of East Africa Particular attention will be given to the search for evidence of an archæological or palæontological nature bearing upon the problem of the antiquity of man in the area, in the hope of extending further northward knowledge supplementing the discoveries made by Dr. L S B Leakey in Kenya and Tanganyika The personnel of the expedition will include two surveyors, Mr R C Wakefield of the Sudan Survey and Mr W H R Martin of the University of Oxford Mr D G MacInnes will be responsible for mammalian palæontology, and Mr J F Millard will act as archæologist Dr W Dyson, medical officer of the expedition, will collect zoological specimens and Mr V E Fuchs, who is the leader, is in charge of geology The work of the expedition, which is supported by a number of learned societies, including the Royal Society, the Royal Geographical Society and the British Association, is planned to occupy about a year

Overhead Line Distribution Outside Great Britain

AT the meeting of the Overhead-Lines Association in London on September 20, the methods used in North America and Scandinavia for distributing overhead lines were discussed. Mr A. L. Stanton, president of the Association, said that it is difficult to make comparisons between the methods used in different countries, as the everyday conditions vary widely In the United States, not more than five per cent of the street lighting is done by gas and not more than 25 per cent of the factory supplies comes from independent stations. The early development of many American supply systems was governed mainly by utilitarian considerations, not much attention being paid to securing continuous service, voltage regulation and avoidance of danger risks.

Mr. T. Stevens described the development of electricity supply in the rural districts of Sweden, Denmark and Norway. Sweden is divided into fifteen areas for the supply of electricity and in most of these the State gives the supply, the remainder being in general owned by a municipality. In the co-operative distribution associations in Sweden, consumers have to hold shares proportional to the acreage of their farms or the number of rooms in their dwelling houses. A certain length of cable is allowed free of charge. When only small supplies are taken, the tariff is greater. Denmark exports to southern Sweden steam-electric power at the times when the water supply is insufficient, and Sweden reciprocates when necessary. In recent years the supply from Sweden has increased from 20 to 90 million kilowatt hours a year. Sweden has 2,387 hydro electric plants. There are three submarine power lines connecting the two countries.

Phosphates in Sugar Fermentation

In his second Liversidge Research Lecture before the Royal Society of New South Wales, Prof. W. J. Young discussed the "Functions of Phosphates in Fermentations of Sugar". Although the production of alcoholic liquors by the fermentation of sugar is older than recorded history, it was only in 1837 that the suggestion was made that the change is due to the living organism yeast. The final proof of this was the work of Pasteur, who showed that the conversion of sugar into alcohol and carbonic acid is a physiological action of the yeast cell. Later on, Buchner discovered that the active principle, or enzyme as it is now called, can be separated from the living cell and will still carry on the action after such separation. Further work has shown that fermentation is a series of chemical reactions in which phosphoric acid plays a part, and during the process compounds between the sugar and phosphoric acid, termed hexosephosphates, are formed. Phosphates play a similar rôle in other biological processes in which sugars are decomposed to simpler compounds, as, for example, in the animal during muscular activity. During muscular work the animal uses up carbohydrate as a source of energy and this is changed to lactic acid, a process which requires no oxygen. Thus an animal can do a certain amount of work without requiring oxygen, as, for example, in a short sprint race. Oxygen is required later on to remove the lactic acid, hence one goes on panting after the effort is over. Fermentation in yeast and lactic acid production in the animal are thus similar changes, the sugar being decomposed through the same intermediate compounds to alcohol and carbonic acid in the former, and to lactic acid in the latter, and for both phosphates are necessary, and the same sugar phosphates are produced.

Work of the National Institute of Industrial Psychology

The *Human Factor*, 7, No. 12, presents the thirteenth annual report on the work of the National Institute of Industrial Psychology. The wide range of subjects dealt with by the Institute is very striking. The report gives brief indications of the work that has been done in factories, school buildings, retail stores, offices and even gold mines and tea and rubber plantations. The underlying problems of lay-out, 'processing' and personnel, etc., appear to have a certain similarity despite the diverse environments in which they are found. In the Research Section of the report, several interesting investigations are worthy of note. Mr. Harding's work on rhythm in occupational movements has thrown open new possibilities in relation to training schemes and the elimination of fluctuations in the speed of work in various occupations; its application to industry in general may be expected to produce far-reaching results. The nature and measurement of the mental abilities involved in factory assembly operations has been studied, and a colour-discrimination test is now ready for use. In addition, various occupational analyses have been undertaken, and the work on vocational and educational guidance has been maintained and extended.

Uses of Rubber in the Home

We have received an interesting and well-illustrated reprint from the *Furnishing Trades Organiser* on "Rubber Flooring and Furnishings". Rubber flooring has been improved both as regards quality and design and the price has come down substantially. The latest type of sponge upholstery is made direct from rubber latex. It is moulded in one piece and obviates the necessity for built-up construction. Sofas, chairs, mattresses and loose cushions are now made of rubber and are stated to be practically everlasting. Lists of companies manufacturing these products are given in the reprint, which is issued by the Rubber Growers' Association (Inc.), 2, 3 and 4 Idol Lane, Eastcheap, London, E.C.3.

Coloration of Fossil Bones

In the September number of *Revue Scientifique* occurs the last of a series of articles upon the coloration of bones which have been for longer or shorter periods buried in the ground. In the present article, L. Franchet deals with the effects upon bones of the boiling of a corpse, and the various colour changes due to incineration. The articles, in which the author discusses experiments he has made to check the effects which occur naturally, should be of value especially to archæologists and prehistorians, particularly in warning against rash deductions regarding the age of buried bones, derived solely from the condition of the bones.

Crystal Structure Models

In the October issue of the *Review of Scientific Instruments*, Mr. G. Glockler, of the University of Minnesota, describes a convenient form of model of crystal structure. The atoms are represented by black, white or coloured dots on vertical sheets of 'Cellophane', which are hinged along their bottom edges to a thin sheet of wood or cardboard and can be folded down for packing. When so folded, each model is about the size of a volume of NATURE.

Standards for Surgical Dressings

THE Pharmaceutical Society of Great Britain has issued a report on "Dressings" by a sub-committee of the Codex Revision Committee (Pharmaceutical Press, 23 Bloomsbury Square, London, W.C.1. 1s. 6d.). It contains a summary of standards for surgical dressings, provisionally accepted for inclusion in the British Pharmaceutical Codex, 1934, which should provide information useful for manufacturers and others. The standards suggested include those for the basic materials, such as jute, silk and wool, and for dressings such as phenol and mercuric chloride gauzes, and others, as well as methods for the determination of moisture, water extract, foreign matter, cotton and wool in the dressings.

Benefits to Animals from Animal Experiments

THE autumn issue of the *Fight Against Disease*, the quarterly journal of the Research Defence Society, contains the concluding portion of Sir Leonard Rogers' Stephen Paget Memorial Lecture. After a survey of some of the principal animal and virus diseases, Sir Leonard concludes that "the examples given from the limited field of tropical medical and veterinary science alone, suffice to prove that the reduction in the suffering that results year by year to animals, as well as to man, from the discoveries made in about three decades through a limited number of animal experiments, is incalculably greater than the pain inflicted on the animals under our humane laws".

Leverhulme Research Fellowships

APPLICATIONS are now invited for Leverhulme research fellowships for 1934. These fellowships are intended in the first instance for the assistance of experienced workers rather than to add to the provision already existing for workers in the early stages of their careers. It has been decided that no definite limit shall be placed to the amount of individual grants, but that they will be adjusted according to the circumstances of each particular case. Fellows will usually be required to work at, or in connexion with, a recognised centre of research, either at home or abroad. No subject of inquiry is excluded from the scope of the scheme. Awards will not be made, as a rule, for a shorter period than three months or for a longer period than two years. The closing date for receipt of applications is March 1. The awards will be announced in July and will date from September 1. All applicants must be British-born and they must also be normally resident in the United Kingdom. Further information can be obtained from Dr. L. Haden Guest, Secretary, Leverhulme Research Fellowships, Union House, St. Martins-le-Grand, London, E.C.1.

Announcements

DR. L. W. G. MALCOLM, conservator of the Wellcome Historical Medical Museum, has been appointed an officer of the Venerable Order of the Hospital of St. John of Jerusalem.

THE following appointments in the Colonial Agricultural Service have recently been made: Dr. F. J. Martin, assistant director of agriculture, Sierra Leone, to be director of agriculture, Sierra Leone; R. S. Ball and J. T. Moon to be agricultural officers, Kenya.

AT the ordinary meeting of the Institution of Electrical Engineers to be held on January 18, at 6 p.m., Viscount Falmouth will present to the Institution a copy of Sir William Orpen's painting of Sir Charles Parsons.

A JOINT meeting of the Royal Astronomical Society and the Geological Society will be held in the rooms of the Royal Astronomical Society, Burlington House, W.1, on January 26, at 4.30 p.m., when a discussion will be held on the "Origin of the Earth's Major Surface Features". The meeting will be presided over by Sir Frank Dyson.

THE annual meeting of the International Society of Medical Hydrology is to be held on January 28–February 2 at Zurich, Davos and St. Moritz. The president elect is Prof. O. Veraguth, professor of physical therapy in the University of Zurich. The principal subjects for discussion are the thermal bath reaction and the physiological and therapeutic effects of high mountain climates. Decisions will be taken concerning the nomenclature and classification of muds, peats, etc., used in physical medicine. The meeting is open to scientific workers generally as well as medical men. Further information can be obtained from the General Secretary, I.S.M.H., 109 Kingsway, W.C.2.

WE have received the 1934 pocket diary of Messrs. John G. Stein and Co., Ltd., silica and firebrick manufacturers, of Bonnybridge, Scotland. The diary contains many features of interest, for example, chemical analysis of various types of firebrick; special refractories, their analyses, expansion curves, thermal properties, etc.; equilibrium diagram of the system $Al_2O_3 - SiO_2$ (Bowen and Greig), first aid treatment; standards of measurement, and their equivalents, sectional road maps of Great Britain, and much other useful standard information.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An examiner in the aeronautical Inspection Department of the Air Ministry—The Secretary (S.2), Air Ministry (Jan. 15). A maintenance and test engineer in the Public Works Department, Electricity Branch, Government of the Punjab—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (Feb. 1). A demonstrator in dairy husbandry and an advisory entomologist in the Department of Agriculture, University of Leeds—The Registrar (Feb. 2). A head of the Departments of Municipal Engineering in the Manchester Municipal College of Technology—The Registrar (Feb. 5). An agricultural chemist and an entomologist at the Imperial Institute of Agricultural Research, Pusa—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (Feb. 12).

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Refraction of Ionised Media

IN a recent letter Prof. Hartree[1] has directed attention to certain difficulties in the theory of refraction as applied to ionised media, and has criticised previous letters by Tonks[2] on the subject. I have myself been occupied for some time in trying to clear up this matter, and can confirm Hartree's opinion of the subtlety of the subject, but at the same time it should be said that, in spite of the defective proof, Tonks's result is certainly right. The problem is whether the formula of Sellmeier or that of Lorentz should be applied for a gas composed of free electrons moving among ionised atoms, which may be taken as fixed protons without losing the point of the question. The refractive index n is to be derived from atomic characters, and the problem is whether it is

$$S = n^2 - 1, \qquad (1)$$

or

$$L = 3(n^2 - 1)/(n^2 + 2) \qquad (2)$$

which is directly related to these. The alternatives for the ionosphere are whether it is S or L that is equated to

$$-Ne^2/\pi m v^2 \qquad (3)$$

where N is the number of electrons per c.c., v the frequency of incident waves, and e and m, the charge and mass of the electron respectively. If the formulæ are used to estimate the actual electron density of the ionosphere, there is a discrepancy of 50 per cent according to which of them is adopted, so that the question is by no means trivial. The same problem arises with even greater force in connexion with the optics of metals. It has been discussed by Kronig and Groenewold[3], their defence of the use of S is open to exactly the same criticism as that of Tonks, but from the known values of the optical constants of metals it is here even more certain that S is the correct form.

The essential point of the question consists in making the correct allowance for the mutual forces between the various particles concerned in scattering the light. The question is one in which we do not anticipate any great difference between classical and quantum theory, and it is easier to work with the classical; in the quantum theory of metals it has been usual to consider what is in effect only a single electron, and this cannot possibly throw any light on the present question. The main difficulty lies in estimating the large influence on each electron of its close neighbours, both protons and electrons. Tonks tries to overcome this difficulty by replacing the protons by a uniform distribution of positive charge-density, but this replacement is the crucial point of the problem; it is only done by an illegitimate inversion of the order of integrations, and this inversion leads to a large change in the resulting value. Unrigorous processes, like the inversion of integrations, are so habitually done in physics with impunity, that one is apt to trust them completely; with an unrigorous formulation of the present problem it is easy to find entirely plausible arguments leading either towards L or S. It is quite easy to show that a set of electrons moving in a uniform positive medium will obey a formula in S, and everyone agrees on this; the whole difficulty is to justify the replacement of the protons by the continuum, for there is little resemblance between the smooth motion of an electron in the continuum, and the zigzag path among the protons.

The technical problem of discussing with rigour the optics of a finite volume of any material is formidable, for it demands retarded potentials for the mutual forces of each pair of electrons, and so the system cannot be taken as a self-contained dynamical system, but must be treated with the help of Lorentz's device of making a fictitious spherical cavity round each electron. Most of the difficulty can, however, be avoided by the device of taking a small isolated sphere of the material and calculating the light it will scatter to a distance. If the radius a is much smaller than the wave-length of the incident light, there is no need to allow for retardation and the whole sphere can be regarded as a single dynamical system. A simple optical calculation shows that under incident light of amplitude A, it scatters light as though having electric moment

$$A\,a^3\,(n^2 - 1)/(n^2 + 2),$$

and therefore n is found if we can calculate the moment directly. For a set of separate elastically bound electrons, as in neutral atoms, there results at once a formula in L; at the opposite extreme, with a continuum of positive electricity, an equation is easily formed for the electric moment which leads to a formula in S. The important question is how the moment behaves for a set of discrete protons lying arbitrarily throughout the sphere. This is not the place to discuss details, but it can be seen that the average motion will satisfy the same equation as in the case of a continuum, provided that each electron undergoes many collisions during the period of the light. This condition is satisfied in the ionosphere for the long waves used, and in metals for ordinary light, so that S is the right expression in these cases.

As a general comment, it seems natural that S rather than L should be the more fundamental formula. Lorentz derived L by introducing a spherical cavity that was quite fictitious, and yet the algebraic form of (2) shows clear evidence of a real sphere. The reason is that there is a genuine sphere (or perhaps some other shape arbitrarily orientated) round each molecule; this is its own surface which prevents the entry of other molecules, and it is the existence of this small real sphere, and not the comparatively large fictitious sphere of Lorentz, that is responsible for (2). S is the natural formula for pure electromagnetic systems, and L is an expression of the fact that the systems to which it applies are governed by a law that is not electromagnetic—the exclusion principle which prevents one atom from penetrating another.

A New Hard Component of the Cosmic Ultra-Radiation

THE Steinke apparatus, which recorded the ionisation caused by the cosmic ultra-radiation at Abisko in northern Sweden during the polar year 1932–33[1], was moved in the middle of July to the iron ore mine Kirunavaara, near Kiruna, in order to record the absorption curve of the cosmic ultra-radiation below various thicknesses of iron ore. The Kirunavaara mountain is pierced at different levels by numerous galleries with rail tracks, some of which follow the ore body through its whole length (4 km.). It was therefore possible to move the apparatus, placed on a wagon or trolley, below layers of pure iron ore of different thickness from 160 to 10 metres, corresponding to water equivalents of 800–50 metres (the specific gravity of the ore being 5). Above the ore is only the atmosphere.

During three weeks in July there were holidays in the mines, and the management kindly lent me an electric train for the investigation of the cosmic ultra-radiation in the main galleries of the Kirunavaara mountain. The apparatus and a lead shield of 10 cm. thickness were assembled in a wagon and kept at constant temperature, and the wagon was moved below thicknesses of 107–60 metres of ore. It immediately appeared, however, that the ore sends out an unexpected and rather strong penetrating radiation; later investigation showed that the ore in this gallery had a radium content up to 0·05 mgm. per ton. (So far as I have been able to find from the literature accessible to me, this is the first time that radium has been found in iron ore.) Also the air in the gallery was highly radioactive and increased the ionisation within a 10 cm. lead shield to values which were impossibly high for the cosmic ultra-radiation. Nevertheless, if these values were reduced to their equivalent in radium radiation (which was taken up without shield), they showed an increase with decreasing thickness of the ore, and this increase indicated an absorption coefficient of the cosmic ultra-radiation about ten times less than that of the hardest component found by E. Regener[2]. At the beginning of August, V. F. Hess, W. Kolhorster, E. Regener and E. Steinke were privately informed about this result.

In order to eliminate the radium radiation, especially that from the air, special precautions and arrangements were necessary for the following measurements. A large airtight iron box of the dimensions 120 cm. × 80 cm. × 85 cm. was constructed containing two chambers, one above the other. This box was placed upon a trolley and in the lower chamber the ionisation cylinder of the Steinke apparatus was placed within a lead shield of 20 cm. thickness open upwards. Before the microscope was a window, and the photographic recorder was placed outside the box before this window. The airtight floor of the upper chamber was laid directly upon the lead shield, and upon this floor the upper lead shield of 10 or 20 cm. thickness was placed. Also the upper chamber could be made airtight. At the request of the management of the mines, measurements of the radium radiation were also carried out, and therefore the ionisation was recorded both with the shield open above (that is, with no shield in the upper chamber) and with shields of 10 cm. and 20 cm. above. During a month and a half, seven series of measurements were taken below 13–104 metres of ore; one series was taken without a shield in the upper chamber in order to get the radium radiation. The apparatus stood generally twenty-two hours at every place in every series and recorded the ionisation during every hour.

As might have been expected with respect to the radioactive air enclosed in the box, the values decreased steadily until the last two series, but the differences between daily values and the corresponding values of the last series were found to fit closely to the curve of decreasing radium emanation as given by Meyer and Schweidler[3], so that daily values could be accurately reduced for this air radiation. The values were further reduced for some radium radiation, which entered around the microscope, where it is impossible to make the shield as thick as elsewhere. The resulting mean values of the cosmic ultra-radiation plus the zero ionisation of the apparatus are: below 13 m. ore, 0·1346 J; below 28 m., 0·0615 J; below 53 m., 0·0402 J; below 75 m., 0·0374 J; below 86 m., 0·0366 J; and below 104 m., 0·0366 J.

Irrespective of the value of the zero ionisation (*Restgang*), these numbers indicate three components of the cosmic ultra-radiation penetrating 13–86 metres of ore, and the softest component has an 'apparent' mass absorption coefficient of $(\mu/\rho)_{H_2O}$ 0·00020 cm.^{2} gm.$^{-1}$, that is, is identical with the hardest component of E. Regener[2] ($\rho = 5$, $(\mu/\rho)_{H_2O} = 1{\cdot}19\,(\mu/\rho)_{Fe}$). The coefficients of the two harder components are rather sensitive to the magnitude of the zero ionisation, the exact value of which is not yet known but will be observed by the forthcoming measurements below 160 metres of ore at a deeper level of Kirunavaara. The zero ionisation cannot, however, be much less than the value now observed, namely, 0·0322 J., and, taking 0·0300 J. as preliminary value, we obtain as apparent mass absorption coefficients of the two still harder components: $(\mu/\rho)_{H_2O} = 0{\cdot}00011$ and 0·00003 cm.^{2} gm.$^{-1}$ respectively. The first coefficient agrees rather well with that recently found by W. Kolhörster[4] $(\mu/\rho)_{H_2O} = 0{\cdot}00013$ cm.^{2} gm.$^{-1}$, but the second coefficient indicates a hitherto unknown component, much more penetrating than the others, and the existence of this hardest component seems well established by the present measurements. The exact mass absorption coefficients will be calculated, when the zero ionisation has been determined below 160 metres of iron ore.

Cosmic Rays and the New Field Theory

REGENER[1] has found that cosmic rays can be observed at 230 m. below the level of Lake Constance. If these rays, as is generally assumed, consist of electrons (not of protons) the great penetrating power raises a serious difficulty in the adopted theory of electronic motion, that is, Dirac's equation. Using this equation, Heitler and Sauter[2] have shown that a beam of very fast electrons (with an energy $E > 200\ mc^2$) should penetrate not more than 1 m. of water when all kinds of absorption processes are taken into account.

The new field theory proposed recently[2] seems to be able to give the explanation of the high penetrating power of very fast particles, either photons or electrons. In this theory there are two types of field vectors, B, E, and H, D, which are identical for very weak fields only. They are different for strong fields, especially in the 'interior' of the electron. The true charge is always concentrated in points, that is, $\operatorname{div} D = 0$, $\int D_n d\sigma = 4\pi e$. But, as has been shown by my colleague, Dr. L. Infeld, a 'free' charge can be introduced with a finite space density, given by $\operatorname{div} E = 4\pi\rho$. This can be considered as the source of the electronic field and as the charge upon which the external field acts, as in Maxwell's theory. For an electron ρ is given by

$$\rho = \frac{e}{2\pi r_0^2} \frac{1}{\frac{r}{r_0}\left(1+\frac{r^4}{r_0^4}\right)^{3/2}}$$

and the space integral of ρ is equal to e.

Under the action of an electromagnetic wave with an amplitude proportional to $e^{2\pi i z/\lambda}$, the behaviour of the electron will be expressed approximately by Dirac's equation provided we replace the charge e by an 'effective' charge $\bar{e}$, given by

$$\bar{e} = \int \rho e^{2\pi i z/\lambda} dV = e f\left(\frac{2\pi r_0}{\lambda}\right), \quad f(x) = \frac{2}{x}\int_0^\infty \frac{\sin xy}{(1+y^4)^{3/2}} dy$$

It is immaterial whether the field be due to a light wave or to the passage of fast electrons; for if $E \gg mc^2$, one has in both cases, with a very good approximation, $\lambda = hc/E$ and

$$x = \frac{2\pi r_0}{\lambda} = 1.236 \frac{2\pi e^2}{hc} \frac{E}{mc^2} = \frac{1.236}{137.1} \frac{E}{mc^2} = \frac{1}{111} \cdot \frac{E}{mc^2}$$

Now the function $f(x)$ is equal to 1, for $x = 0$ (long waves, small energies), but decreases with increasing x. For $x = 2.4$, or $E = 266mc^2$, it is $\frac{1}{2}$, and for $x = 5$ or $E = 555mc^2$, only $\frac{1}{10}$. The cross-section of action, which is proportional to $(\bar{e}/e)^2$, will therefore diminish rapidly with increasing energy of the rays.

Provided the assumption of protons could be excluded, the high penetrating power observed for the cosmic rays may be considered as a confirmation of the new field theory.

The Pre-Crag Men of East Anglia

IT is common knowledge that the Suffolk Bone Bed beneath the Red Crag is made up largely of the remains of a land surface which existed, for a prolonged period, prior to the submergence of East Anglia beneath the sea of Crag times. Sir Ray Lankester pointed out many years ago[1] that the bones and teeth of land mammals found in the Suffolk Bone Bed are of different ages—some being of a Miocene antiquity, while others are to be referred to certain phases of the Pliocene epoch. He was able also to show that the tooth of a mastodon, by reason of its being partly embedded in a deposit of Diestian sandstone, must be older than this Lower Pliocene accumulation, which is represented in the Suffolk Bone Bed by the well-known fossiliferous box-stones. Thus, by these investigations, it was made clear that, so far as the remains of terrestrial mammals are concerned, the contents of the Suffolk Bone Bed are markedly derivative and referable to widely separated periods anterior to the deposition of the Red Crag.

When, some twenty-five years ago, the announcement was made[2] that flint implements had been found in the Suffolk Bone Bed, a considerable body of opposition to this claim was encountered, and, for a long time, it was needful to concentrate upon the primary task of establishing the fact that the pre-Crag flints had been humanly flaked. But it has now become advisable to proceed to the next stage, and to classify these very ancient relics of man with the view of attempting to ascertain their probable geological antiquity. This process of classification has been made possible by the large number of pre-Crag implements now available for study, and, especially, by the excellent specimens recovered recently during excavations carried out on behalf of the Royal Society, the Wellcome Historical Medical Museum and the Trustees of the Percy Sladen Memorial Fund. The critical examination which has been undertaken of the pre-Crag flints is leading to certain unexpected and far-reaching conclusions, which I propose to set forth briefly here.

It can now be claimed without fear of serious contradiction that, at least, four distinct and different groups of flint implements are contained in the Suffolk Bone Bed. This is established by the fact of the discovery of numerous examples of flints exhibiting flaking of more than one period and in which the newer flake-scars definitely cut into and are patinated a markedly different colour from the older. Moreover, it is apparent that the four types of patination represented can be precisely matched by that to be observed upon a series of implements which are each different in their forms and condition. Thus, for example, the oldest artefacts are thick and coarsely flaked, exhibit a peculiarly archaic, washed-out yellow colour and have evidently been subjected to very considerable striation and abrasion. The latest implements, on the other hand, are usually white or light blue in colour, are little if at all abraded, and are not thick and coarsely flaked. Between these groups are two others which in patination, condition and general appearance are equally distinct from each other.

There is, in fact, as much divergence in these matters, between Group 1 and Group 4 of the pre-Crag implements, as there is, for example, between the Early Chellean and Late Acheulean hand-axes. It is possible also that the gap in time between Group 1 and Group 4 of the pre-Crag industries is greater than that separating the palæolithic implements mentioned. This supposition is based upon the 'morphology' of the former specimens, the thickness and consequent antiquity of the various patinated surfaces, and the fact that there has now been found beneath the Red Crag a well-made rostro-carinate implement which has attached to various parts of its surface areas of material which, so far as a very careful visual examination goes, is indistinguishable from Diestian sandstone.

The manner of distribution of this deposit upon the implement makes it highly probable that the specimen was at one time embedded, like the mastodon tooth described by Lankester, in a Diestian nodule, and must therefore have been made at some period prior to the laying down of this Lower Pliocene stratum. Moreover, the patination of the flake-scars of the rostro-carinate in question is precisely similar to that to be observed upon others which are clearly later in date than the flaking of Group 1 of the pre-Crag implements It would seem to be necessary therefore to relegate the latter to an epoch still further anterior to the Diestian period than is the rostro-carinate to which reference is made

If these conclusions are sound, they give us much additional information upon the question of the antiquity of man. The earliest flint implements in this bed, which comprise primitive though well-made specimens, including rostro-carinates, referable apparently to some at present unspecified period preceding the Diestian, seem definitely to surpass, in their forms and flaking, the type of artefact which, it may be supposed, would have been produced by the most lowly representatives of the human race. The implements of Harrisonian eolithic form associated with Group 1 of the Suffolk Bone Bed specimens were at one time thought to be actually comparable with the well-known Kentian eoliths. But it now appears that the pre-Crag examples are mostly made from intentionally struck flakes and thus represent a more advanced stage of human achievement than do the true Harrisonian implements.

Thus it seems reasonable to conclude that prior to the laying down of the Suffolk Bone Bed, which must pre date by a considerable period the earliest palæolithic civilisations, various races of flint flaking people inhabited the ancient East Anglian land surface. It is clear, from an examination of the pre-Crag implements, that they must be much older than the marine sands under which they now lie, and it is possible that the most ancient groups of artefacts date back to epochs earlier than that known as Diestian. After a very careful consideration of the whole matter, I believe that this is indeed the case, but in order to give all those interested an opportunity for coming to their own conclusions, the large collections of pre-Crag implements in the Ipswich Museum have now been re-arranged upon the lines indicated in this note and can be freely examined by responsible visitors. A representative selection from the four groups of specimens has been arranged as a loan exhibition in the British Museum, and I hope to publish a fully illustrated paper dealing with these implements.

Science and Politics

ALL scientific workers will thank Prof. A. V Hill for raising the problem of their status in a world in acute political tension (NATURE, Dec. 23). Most will agree with his main thesis, and few, if any, will hold it to be the duty of scientific societies, such as the Royal Society, to meddle with divinity, metaphysics, morals or politics But this rule applies to the society as a corporate body, and not to its individual members. Those men of science who interest themselves in politics will be unable to agree with Prof. Hill's contention: "If scientific people are to be accorded the privileges of immunity and tolerance by civilised societies, however, they must observe the rules". I am glad to think that individual fellows of the Royal Society, at any rate, have consistently disregarded these rules. Among its earliest fellows, Pepys and Brouncker, to mention no others, meddled in politics; in the eighteenth century, Franklin and Priestley meddled even more conspicuously

Everyone recognises the difficulty of keeping emotion out of one's scientific decisions when they have a political bearing But does Prof Hill condemn scientific men who investigate human heredity because their results discredit the theory of the equality of man, or those who investigate human diet because they demonstrate that a considerable section of the British working classes is underfed? Science could "remain aloof and detached", to use his words, so long as it only concerned itself with man as something to dissect That day is past

Prof Hill condemns the irrational character of certain modern political movements May it not be that the remedy for this lies simply in the application of scientific thought to political and moral problems? It is obvious that such an attempt will endanger the immunity which scientific workers enjoy so long as their opinions are regarded as politically unimportant. But science is in any case in danger of perishing during a general collapse of our political and economic system If we refuse to apply scientific method to human affairs because they are inevitably tinged with emotion, we may help to precipitate this collapse. Such application will be very largely critical, in so far as many political doctrines are based on hypotheses which cannot stand scientific criticism, but it must be to some extent constructive, as when it is pointed out that, owing to defects of Nature and nurture, some men and women cannot play an adequate part in society, and remedies for this state of affairs are suggested.

I do not see why a man of science who "meddles" with such matters should thereby forfeit a right to tolerance, and question whether Prof Hill has done a service to science by penning a sentence which might be interpreted as meaning that his profession should only be tolerated in so far as it is muzzled His subsequent eulogy of independence of thought and speech make it clear that his meaning was quite otherwise. But many of his colleagues will continue to feel that, while scientific societies should restrict their activities to the purest science, their members have not merely the right, but even sometimes the duty, to interest themselves in more controversial matters.

J. B. S HALDANE.

John Innes Horticultural Institution,
London, S W 19.

OF course I would not condemn scientific men who investigate human heredity, whatever their results may discredit, but I should advise them to avoid an emotional bias towards any particular political or social theory which may be affected by their investigations: otherwise experience teaches that their results are suspect Of course I should not condemn scientific men for studying human diet, but the motive should be the discovery of scientific fact, not the demonstration that the British working class is underfed

Prof. Haldane fails to distinguish between "people scientifically trained" who, I urge, "should take some part in affairs" and the scientific investigators themselves. It is perilous, as I said, to disregard the scientific basis of modern civilisation, and all educated men should have some direct appreciation of the methods and ideas of science. This is exactly what Prof. Haldane himself urges in his third paragraph. It is the application of scientific methods to politics and social affairs, and the increase of scientific education and outlook, not the interference of specialist scientific investigators with matters outside their own special competence, which may avert the dangers of which both Prof. Haldane and I are aware. A reputation gained by scientific achievement, and the immunity accorded to scientific pursuits, should not be lightly used to extort consideration in other respects. One may not approve of political intolerance, but one may recognise as a fact that eminent scientific men do well, in the interests of science, to avoid meddling with morals or politics."

Methods of Ionospheric Investigation

Prof. E. V. Appleton[1] has described a method of measuring the maximum ionisation existing in the lower region of the ionosphere. It is clear from recent work[2,3,4] that, in order to investigate ionospheric fine-structure in sufficient detail, our technique must be improved along at least two lines:—

(1) The time taken in making a measurement of ionisation density should be as short as possible.

(2) Measurement of the equivalent path of the atmospheric rays should be made over a frequency range which is continuous.

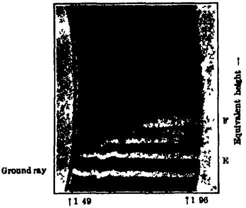

Fig. 1. Frequency in megacycles/sec.

The complexity and sudden changes in ionospheric conditions observed in the polar regions would have made an apparatus embodying such improved technique a powerful instrument in our investigations. The transmitter and receiver were about ten miles apart, so that any form of mechanical linkage or remote control was not practicable. As a result of attempts to meet the requirements, the method finally adopted consisted in increasing continuously the frequency to which the transmitter was tuned and causing the tuning of the receiver to vary in synchronism. The scheme, although not ideal, enabled (2) to be satisfied over a limited frequency range and an approach towards (1) above. The time taken to make one picture (such as that reproduced as Fig. 1) involving a determination of the ionic density was two minutes. The calibration frequency marks which appear on the records were made by attaching a contact arm to the condenser spindle of the high-frequency oscillator of the superheterodyne receiver and arranging that each time this condenser dial responded to the particular frequencies marked on the records, the incoming signals were cut off and a local calibration from a 2·5 kc./sec. time-base was switched on. This condenser spindle was turned uniformly so that it is possible to interpolate between calibration marks on the record.

Records which will show the importance of this type of observation will be published amongst the results of the British Polar Year Expedition to Tromsø. One specimen is reproduced here to illustrate the importance of (2) above. It is a record taken at midnight during the period of the 'midnight sun'. The calibration marks on the left of the picture are caused by a 2·5 kc./sec. oscillator so that the distance between two successive marks corresponds to 0·4 milliseconds or an effective height of 60 km. The picture shows the ground ray and echoes from the *E* region, intermediate region and *F* regions of the ionosphere. There is also a considerable amount of scattering visible. The frequency range shown is only 0·5 mc./sec., but it will be seen that the echo pattern changes greatly over this comparatively small amount. At 1·49 mc./sec. the *E* echo is prominent with a small amount of reflection from the intermediate region. This latter increases with frequency up to 1·93 mc./sec. At 1·7 mc./sec., marked reflection begins from the *F* region and continues to the highest frequency shown. The picture gives some idea of the complexity of the ionosphere in the polar regions.

This work was carried out in May 1933 at Nordlysobservatoriet, Tromsø, as part of the Polar Year programme of the Radio Research Board, and I am indebted to Hr. Harang, director of the Observatory, for the loan of apparatus and for experimental facilities which made these results possible.

Liquids of High Refractive Index

In measuring the refractive index of precious stones, we have succeeded in extending the range of the total reflectometer type of instrument by the preparation and use of liquids of higher refractivity than the sulphur in methylene iodide solution ($n_D < 1·79$) which is usually employed to make optical contact between the stone and the glass hemisphere of the instrument. The various immersion media of high refractive index proposed by Merwin[1] and Wright[2] were found to be unsuitable. Of a number of compounds prepared the following are worthy of note.

1. Tetra-iodo-ethylene, C_2I_4. This compound dissolves readily in methylene iodide (22 per cent at 15° C.) and with sulphur in this liquid forms a stable clear solution, n_D 1·81, well adapted for routine use with the refractometer[3].

2. Phenyldi-iodoarsine, $C_6H_5As.I_2$. Prepared by the method of Steinkopf and Smie[4] it is a clear orange liquid, d^{15° 2·56, with a high refractive index and dispersion, as shown by the following mean values:

$\lambda(A)$	6708	6438	6141	5893	5535	5350	5106
n^{15°	1·822	1·828	1·835	1·843	1·856	1·865	1·879

Phenyldi-iodoarsine has a blistering action when in contact with the skin, but, handled carefully, provides an excellent liquid for use with the refractometer, and should prove valuable as an immersion medium.

3. Selenium monobromide, Se_2Br_2, has a higher refractive index than that of any pure liquid hitherto recorded. Prepared by direct combination, the value for n_{Li} is 1.96 ± 0.01 rising to 2.02 on exposure to the atmosphere, owing to decomposition of the bromide, with separation and reabsorption of selenium. It is opaque, except in thin films, to all but deep red light, but when mixed with methylene iodide can be used with the refractometer. To obtain a high reading we find it convenient to mix the selenium-saturated bromide with the special methylene iodide solution mentioned above, in small quantities as required. Such mixtures have $n_D > 1.90$ and thus enable readings to be made up to the limit imposed by the refractive index of the glass hemisphere of the instrument (no instrument reading above 1.90).

To make still higher readings possible we hope that fine quality transparent zinc blende (n_D 2.37) may be worked and used in place of the glass, the instrument being suitably modified. Further work on this subject is in progress.

Crystal Structure of 1-3-5 Triphenylbenzene

A PAPER has recently appeared[1] in which a structure is proposed for 1-3-5 triphenylbenzene, based on X-ray measurements. The unit cell has dimensions $a = 11.2$, $b = 19.8$, $c = 7.6$ A., and contains 4 molecules. No reflections were observed from planes $(h0l)$ where l is odd, and $(hk0)$ where $h + k$ is odd. On the assumption that the crystals are orthorhombic bipyramidal, this would mean that the space-group is Q_h^{16} (P*mcn*) and that the molecule has a plane of symmetry. The authors place this plane of symmetry parallel to (010), but it is clear from the 'absent reflections' that (010) and (001) are both glide-planes of symmetry and that the molecular plane of symmetry, if it exists, must be parallel to (100). This result is incompatible with the authors' structure and also, as it happens, with the most probable dimensions of the molecule and the actual intensity data.

The explanation of this apparent anomaly is that the crystal class is not orthorhombic bipyramidal, but orthorhombic pyramidal. The crystals show a small, but quite definite, piezo-electric effect, indicating that the crystallographic 'a' axis is, in reality, a polar axis. The molecules are *asymmetric*, though pseudo-trigonal, and the plane of the benzene rings is not coincident with the crystallographic (001) plane, as in the proposed structure, but makes a small angle with that plane. A complete account of the correct structure, based on accurate X-ray intensity measurements, together with optical and magnetic data, will be published shortly.

Meanwhile the importance of making piezo-electric measurements whenever possible cannot be too strongly emphasised, as lack of knowledge may otherwise lead not only to the assumption of too much molecular symmetry, but also to a completely incorrect structure. It is, I think, a fact that in every case for which a plane of symmetry in the benzene ring has been reported, the presence of a piezo-electric effect (not tested for) would eliminate that plane.

A New Wound Parasite of Potato Tubers

IN a recent communication, Mr. S. F. Ashby of the Imperial Bureau of Mycology, Kew, informs me that he has not been able to find a record of *Fusarium viride* (Lechm.), Wr. on potato or of any tests of its parasitism on that host. Recently Wollenweber[1] has renamed it *F. solani* var. *medium*, Wr., but its pathogenicity does not appear to have been tested.

Single spore cultures of *F. viride*, kindly identified by Dr. Wollenweber, were inoculated into potato tubers by a slightly modified method of Granger and Horne[2]. After 24 days at room temperature (20°–25° C.) all the inoculated potatoes showed a well-advanced dry rot with a wrinkled sunken patch and whitish pustules on the surface near the plug. The fungus was re-isolated in a pure form both from the diseased parts as well as from the pustules. Its saltant was as virulent as the parent. *F. moniliforme*, *F. camptoceras*, *F. diversisporum*, *F. semitectum* and *F. semitectum* var. *majus* failed to infect the tubers. The controls all remained healthy.

Scurvy in the 17th and 18th Centuries

THERE is an English seventeenth century reference to the treatment of scurvy, which, perhaps, is not so well known as it might be. John Woodall, author of "The Surgeon's Mate, or Military and Domestique Surgery", 1639, wrote on p. 171, "juyce of lemmons was ever reputed a cold medicine, prescribed and given daily by physicians in burning and pestilentiall fevers, and that with good reason and good successe even to this day, and yet to that notable and cold and terrible disease of the Scurvy, how excellent hath it been approved . . ."

In the next century, Capt. Cook did not find citrous fruits to be of striking value, for a very good reason arising from the nature of his supplies. There is appended to his paper in *Phil. Trans.*, vol. 66, 1776, a letter in which he writes: "I have no great opinion of them alone", 'them' being oranges and lemons, preserved as a 'rob' or syrup of *boiled* juice.

Research Items

China and the Maya. A communication from Dr. Kiang Kang-Hu on the resemblances between the Maya civilisation of Central America and that of the Chinese, accompanied by an introductory note, dealing broadly with the question of cultural diffusion across the Pacific, by Dr. W. D Lighthall, has appeared (*Trans. Roy. Soc Canada*, Ser 3, 27, Section 2) Dr. Kiang from his familiarity with the cultures of his own and kindred peoples is able to bring forward a number of instances, in which he sees resemblances between the two civilisations, for the further scrutiny of specialists Among these are the physical characters and the mental outlook of the two peoples, the Maya more nearly resembling the Chinese physically than any other of the aboriginal tribes of Central and North America He also points to similarities in language, in the complicated and elaborate calendrical system, both peoples using the 'large' and 'small' month count Their religion and deities, sacrifice and worship are also alike, especially in regard to the use of idols of wood and clay to which human blood was applied. China, however, does not appear to have practised human sacrifice, although there are traditions of it in ancient days and remote parts The astronomical and astrological systems are strikingly similar; and the creation legends of the two peoples have many common features, as also have the story of the deluge and of the creation of the first men out of mud Art, dress and ornament are reviewed with the same result Setting aside the elements which are common to many primitive peoples, many resemblances remain which cannot be dismissed lightly If the Mayas were of Chinese origin, they must have crossed to America more than six thousand years ago, otherwise their culture would be more specifically Chinese Alternatively, they may have been derived from other adjacent races, different from, but culturally related to, the Chinese.

Phylogeny of Hemiptera–Heteroptera. In describing a new family, Leotichidæ (*Ann. and Mag Nat Hist*, Ser 10, 12), W E China discusses the general classification of Hemiptera–Heteroptera and proposes a hypothetical phylogenetic arrangement of the 51 families at present recognised within this suborder This arrangement is compared with the latest attempt by Pruthi (*Trans Entom Soc*, *London*, 1925) to revise the family classification solely on the basis of the morphology of male genitalia It is stressed that there are no grounds for assuming that genitalia are less affected by environment and habits than are other characters. Indeed, the fact that whole groups of species exist which differ only in genital structures would seem to indicate that often these structures are the first to be affected It is only the general plan of genital structures which is of value in supplying important clues to the phylogeny of the group. The two main types of genitalia, those of the pentatomoid and reduvioid groups of families respectively, follow the biological difference in feeding habits, members of the first group being mainly phytophagous, and those of the second mainly predaceous. Nevertheless, the primitive Heteroptera were undoubtedly phytophagous, not predaceous, and were homopteroid in character. The family Corixidæ contains the only aquatic phytophagous Heteroptera, and it is considered to represent the aquatic form derived from those ancestors, whereas the true aquatic bugs (as opposed to the littoral and surface forms) arose from predaceous terrestrial forms of the littoral type, at a much later date A biological sequence showing a gradual change from littoral life to a truly aquatic existence is traced from family to family, and a 'family tree' including all known families serves to illustrate the interesting discussion.

South American Lizards. A preliminary check list of the lizards of South America has been compiled by Charles E and May Danheim Burt (*Trans. Acad. Sci. St Louis*, 28, Nos 1 and 2; 1933). The authors consider that probably, in their catalogue of 86 pages, they have listed too many rather than too few species, and that great systematic modifications of the present groupings must ultimately be made. But the list should stimulate field work and research on South American lizards, the more so since the distribution of even common species is not precisely known, and since little has been published concerning the habits and habitats of any

Reproductive Apparatus of *Thalassema*. P R Awati and D S Deshpande (*J Univ. Bombay*, 1, Pt. 5, 1933) describe the reproductive apparatus of *Thalassema bombayensis* The single gonad is around the posterior part of the ventral vessel, and from it fall into the cœlom clusters of cells which in males develop into sperm morulæ while in females one cell in the centre of each mass enlarges and becomes an ovum growing at the expense of the sister ova. There are usually four pairs, occasionally five pairs, of gonoducts in the anterior region of the body. Each organ consists of a vesicle into which opens the common duct of two spiral 'flagella'; from the vesicle issues a short duct which opens to the exterior The vesicle is small in immature examples but in mature specimens is distended with the sexual cells. Each 'flagellum' is ciliated along its margins and along its length has a ciliated groove. The two 'flagella' meet and fuse, the two grooves forming a common duct which opens into the vesicle; near this the short duct leads from the vesicle to the exterior. The sexual cells are brought from the cœlom into the vesicle by the ciliated grooves of the 'flagella', accumulate therein and finally pass to the exterior by the short efferent duct. The authors regard these 'segmental organs' as cœlomoducts

Fungi of Butter. Many of the taints and faults of butter are due to the activities of fungi. This fact has led workers in several countries to study the fungi which occur naturally or appear during the manufacture of this product. A very complete list is published in vol. 9 of the *Canadian Journal of Research* ("The Fungi found in Butter", by G. R. Bisby, M C. Jamieson and M. Timonin, pp. 97–107, Aug 1933) Samples of butter from all the creameries in Manitoba were tested for the presence of fungi. One creamery produced butter with no moulds, and the product was of excellent flavour. A long list is given of all the fungi isolated from other samples, not only by the authors, but also by other workers on the same subject, and should prove valuable to dairy workers for reference.

Mesozoic Pteridosperms from South Africa. In a recent publication (*Phil. Trans Roy. Soc. London*, B, 222) Dr. Hamshaw Thomas gives an account of some remarkable fossil plants from rocks of Triassic Age in Natal which notably extends our knowledge of Pteridosperms as constituents of post-Palæozoic floras. He describes an interesting set of seed-bearing and pollen-bearing fructifications which, by evidence of cuticular structure, other morphological considerations, and close association, he is able to relate to one another and to such well-known form-genera of fronds as *Thinnfeldia*, *Dicroidium*, *Pachypteris*, etc., fronds which have for some time been suspected, without adequate evidence, of being pteridospermous. These he groups into two families (1) the Corystospermaceæ, characterised by having seed-bearing branches with terminal recurved cupules each of which bears a seed with a curved bifid micropyle. The pollen-bearing branches bear their microsporangia in groups on small laminæ, and the microspores, which have also been found adhering to the nucellus in the seeds, have two lateral, symmetrical wings and closely resemble those of *Antholithus* in the Caytoniales. The foliage probably was of the types known as *Dicroidium* and *Pachypteris*. (2) The Peltaspermaceæ, a closely allied family, have seed-bearing branches with the seeds attached to small peltate terminal expansions of the axis. The foliage was of the *Lepidopteris* type but the pollen-bearing structures have not as yet been identified. These discoveries have an *important bearing on the question of the* possible origin of the Angiosperms from a Pteridosperm stock and on the morphological nature of seed-bearing structures in general.

Artificial Vibrations of the Ground. Some interesting experiments on this subject, made by S. K. Banerji and M. D. Manohar, are recounted in the *Indian Journal of Physics*, 8, 95, Sept. 1933. An iron ball of about 28 lb. weight was dropped on to the ground from a height of about one yard, and the resulting ground vibrations were measured by two horizontal component (north-south and east-west) Milne-Shaw type seismographs (period 12 sec., damping ratio 20 · 1) and a vertical component seismograph (period 3 sec.). Records were taken when the point of impact was in different directions from the small seismograph house, and at numerous distances up to about 50 yards. The records show a sudden impulse followed by oscillations compounded of forced vibrations of the ground (period 0·05 sec.) and the free period of the seismograph house (0·015 sec.). Using a theory given by Lamb, the ground vibrations, and their law of variation of amplitude with distance (proportional to 1/√distance) can be reasonably well accounted for. The free period for the building also agrees with a theoretical estimate.

Landing of Aircraft by Radio. The October *Bulletin of the Bureau of Standards* contains a description of the complete form of the equipment for enabling aircraft to land in fog or other conditions of low visibility. The methods have been developed since 1928, and have now been incorporated into a practical form and tested by repeated use in actual fog and in an aeroplane with hooded pilot's cockpit. The course of the aircraft is directed to the airport by a beacon station using a 200–400 kc. frequency and a visual indicator on the machine. The intensity of the beacon signals provides an approximate indication of the distance from the airport on a milliammeter graduated in miles. When several miles from the airport, the machine picks up a landing beam from a special short-wave transmitter (10,000 kc. frequency) which is arranged so that a surface of constant signal intensity is a sloping path down which the aeroplane may glide. The signal intensity meter on the aeroplane is combined with the beacon indicator, so that the pilot needs only to keep the two pointers intersecting over the centre of the dial by movements which easily become intuitive. As the machine approaches the airport it picks up a marker signal beam modulated with a distinctive tone and directed vertically at a position a few thousand feet from the landing field. At the edge of the field itself a second distinctive marker tone is heard. The aeroplane is then only a few feet from the ground and a landing may be effected without difficulty (see also NATURE, 132, 925, Dec. 16, 1933).

Helium in Beryl. Lord Rayleigh (*Proc. Roy. Soc.*, Nov.) has made determinations of the helium content of a number of specimens of beryl of varying geological age. The beryls were finely powdered and decomposed with molten caustic potash at about 300°; the gas was purified and measured over mercury in a McLeod gauge. The beryls obtainable were predominantly from Archæan formations, but a number of specimens were classified as Palæozoic, Mesozoic or Tertiary. Within each group the helium content was very variable, but the helium content showed a definite tendency to *increase* in *going from* younger to older specimens. The largest helium contents were limited to specimens of great geological age. The conclusion appears to be that the helium has accumulated in beryl during geological time, and that it was not trapped when the mineral was formed or produced by the disintegration of short-lived radio elements during the early life of the beryl.

Holley-Mott Continuous Counter-Current Washery and Petroleum Products. In a paper read on November 14 before the Institution of Petroleum Technologists, Mr. E. Thornton maintained that sponsors of the Holley-Mott continuous counter-current washery for the treatment of cracked spirit were justifiably proud of the good results achieved with this plant, the usefulness of which is determined solely by the application of generally accepted principles in the most straightforward manner. All good treating plants must be so designed as to be capable of mixing reagent and treated material in suitable proportions, maintaining the admixture for a given length of time and separating reagent and treated material at the expiration of that time. Intimacy of contact between reagent and treated material is achieved in the Holley-Mott process by means of a vessel containing a suspended stirrer revolving at a moderate speed and with no footstep bearings. Not only is this method of mixing simple and efficient, but it is also definitely economical. The time of contact between reagent and treated material is controlled by the size of the vessel in relation to throughput, as is the case with most continuous plants. Since the degree of mixing is kept definitely under control, the problem of separation is not formidable and is solved simply and cheaply by means of gravity-settling in reasonably-sized vessels. In addition to fulfilling the above main requirements, the Holley-Mott plant satisfies a number of other conditions essential to the effective treatment of spirit.

Annual Meeting of the Science Masters' Association

THE thirty-fourth annual meeting of the Science Masters' Association was held at the Imperial College of Science, London, on January 2–5. More than 600 members attended

This year's president, Mr H T Tizard, Rector of the Imperial College, inaugurated the proceedings, after the annual dinner, with an address on "Science and the Industrial Depression" He referred to the gloomy picture of the immediate future envisaged by Dr Norwood in his presidential address two years ago, and how it had been justified by succeeding events There was a widespread belief that science contributed to industrial depression in creating unemployment by substituting the machine for the man, in discouraging skill by replacing skilled work by unskilled work, and in promoting discord by increasing the powers for evil. The last, however, was a moral question, the decision to use the powers of science for good or evil being dependent upon education

Mr Tizard denied that it was true that the progress of science tended to discourage skill, what it had really done was to replace one skill by others In the matter of increase of unemployment, figures were given for both England and the United States to show that mechanisation actually increased the number of wage earners between 1914 and 1927 The responsibility for industrial depression lay with the economist and politician rather than with scientific workers

It was possible, however, that because of the inertia of industry in times of prosperity, continuous advantage was not taken of new inventions and discoveries of science Consequently, a set-back, due to whatever slight cause, would put into operation widespread economies, and sudden application of scientific labour saving devices that would give rise to the unemployment of many workers who, however, were really superfluous to industry, even in times of prosperity The coal industry was given as an example

To overcome this industrial apathy towards the application of science, it was necessary for science to be added to the mental equipment of administrators, possibly by a combination of science and economics at the universities Moreover, it was the duty of all science masters not only to imbue the gifted few of their pupils with the spirit of intellectual adventure, but also to impart to many the power of observation and the skill of hand that bring interest and happiness to life, and to send all out into the world with a sense of fact and a sense of law

Prof E N da C Andrade in his lecture on new experimental work in sound, dealt with the phenomena associated with Chladni's plate, Kundt's tube and the sensitive flame, and showed by ingeniously simple experiments new facts that could only be explained by new theories. In particular, the vortex theory, which explained the phenomena of Kundt's tube, made possible very accurate measurement of the velocity of sound. It was found that the velocity of sound did in some measure depend upon the frequency and that previously noticed but ignored irregularities in the velocity of sound in the work of other investigators were of significance

The nature of heavy hydrogen and heavy water was the main feature of interest in Prof H V. A Briscoe's lecture on recent advances in chemistry. The nomenclature of the new hydrogen, and its isolation by electrolysis, fractional distillation, or fractional diffusion through palladium were described. The properties of heavy water, f p 3 8° C, b p 101 4° C, density 1 1056, temperature of maximum density 11 6°, its 50 per cent greater viscosity and its biological effects excited great interest, as did the discussion of the theoretical implications in the matter of atomic structure

Dr Allan Ferguson provided a most interesting lecture on London's contributions to science, ranging backwards from Lord Rayleigh, Clerk Maxwell, Faraday, Wollaston, Young, Cavendish and Halley, to Wren and even Chaucer The biographical details of these celebrities were supplemented by interesting historical exhibits

The evening lecture on January 3 was devoted to fungi, by Mr J Ramsbottom, who, starting from yeast and its influence on life's necessities, beer, bread and cheese, proceeded, with the aid of beautifully coloured slides, to demonstrate the difference between edible and poisonous fungi

Very interesting experiments capable of school demonstration, and therefore doubly valuable to the science masters, were shown on January 4 by Mr. H. Haile, in his lecture on the polarisation of light and its application to applied science This was followed by a lecture by Prof A Brammall on geochemistry applied to the genetic study of 'hybrid' rock types—a compact summary of useful information In the evening, the Astronomer Royal, Dr H Spencer Jones, summarised the modern views on the structure of the universe, illustrating his discourse by striking astronomical photographs, particularly of the Milky Way There was a further lecture on January 5 by Prof R A Fisher on adaptation and mutations

It has always been a feature of the annual meeting of the Science Masters' Association for members to exhibit and demonstrate with home-made apparatus new technique, methods and notions developed in the school laboratories Many of these are now found in the "Science Masters' Book", published by the Association This year, the members' exhibition was larger than ever, and full of stimulating ideas A gramophone record used to reflect light, giving rise to interference fringes, 'Cellophane' as a semi-permeable membrane, milk bottles as gas jars, soap bubbles blown in an enclosed space so that they may drain undisturbed in order to demonstrate colours of thin films, were among the striking features

There was a much appreciated innovation this year in that Mr F A Meier was invited to give a lecture demonstration on some of his ingeniously simple experiments, which obviously delighted the lecturer as well as the audience With the aid of toy trucks, thermos flasks, home-made springs, football bladders, balloons, bicycle wheels, pickaxes, flour bins, he demonstrated principles of mechanics, hydrostatics, properties of matter, light, heat, electricity and magnetism Moreover, these experiments were quantitative, and Mr. Meier was able to show that it was usually possible to obtain at least a one per cent accuracy

In addition to these lectures, there were two important discussions, one on the School Certificate biology syllabus, and the other on the elementary science suggested by the School Certificate Investigators' Report as a compulsory subject at the School Certificate stage. This latter discussion will form the subject of a further report

Visits were paid by various members to seventeen factories and Government scientific institutions in and around London These included, among others, the Courtauld Institute of Biochemistry, the Paint Research Station, Government Laboratories, the Royal Observatory, the Royal Aircraft Establishment, and the Royal College of Surgeons These, together with the exhibition of scientific textbooks and apparatus, made a very full programme Twenty-three publishers and thirty-nine manufacturers and thirty-five members exhibited

The next annual meeting will be at Oxford under the presidency of Dr N V Sidgwick F W. T.

Annual Meeting of the Mathematical Association

THE annual meeting of the Mathematical Association was held at the Institute of Education, London, W C 1, on January 4–5, under the presidency of Prof G N Watson Discussions on the place of mathematics in the new central schools, on the interesting and novel suggestion that in the teaching of elementary geometry, solid geometry should precede plane geometry, and on the place of differentials in the teaching of the calculus, showed that the Association has not forgotten its primary purpose, the improvement—if necessary, the reform—of the teaching of elementary mathematics

Under the title "Scraps from some Mathematical Note Books", Prof Watson delivered a lucid and stimulating presidential address It was based on the diary in which C F Gauss (1777–1855), one of the greatest mathematicians of all time, recorded many of his discoveries; Gauss started keeping this diary at the age of nineteen, and it is remarkable that the majority of the hundred and fifty entries were made before 1801

The first entry is the discovery of the possibility of a ruler and compass construction of the regular polygon of seventeen sides, a particular case of a more general problem to which Gauss himself gave a complete answer at a slightly later date There are several entries referring to the quadratic reciprocity theorem, another, prefaced by a triumphant "Eureka", is equivalent to the result that every integer of the form $8m + 3$ is expressible as the sum of three odd squares Other entries mentioned by Prof Watson deal with continued fractions, the zeros of a Bessel function, and a function which is connected with the famous zeta function of Riemann In connexion with this last entry, Prof Watson pointed out that in a copy of Schulze's logarithm tables inscribed "Gauss, 1791", Gauss has made a note which can readily be interpreted as a statement that the number of primes less than a large number x is approximately equal to $x/\log_e x$, this is the "prime number theorem", of which the first proofs were given by Hadamard and de la Vallée Poussin in 1896

In addition to describing these striking results, Prof. Watson gave a brief account of the developments to which these results have led, concluding with a description of some remarkable numerical work connected with the prime number theorem which was carried out in 1933 His general aim was not only to honour Gauss but also to stress the importance to mathematicians of the dictum of N H Abel (1802–29) who, when asked how he had been able to accomplish so much in so short a time, replied. "By studying the masters, not the pupils"

Prof. E H Neville, professor of mathematics in the University of Reading, has been elected president of the Association for the forthcoming year

Research at the Cawthron Institute

THE Cawthron Institute at Nelson, New Zealand, was founded and endowed through the munificence of Mr Thomas Cawthron, who was born in 1833, and after his death his trustees decided that a research institute for the investigation of agricultural problems should be established as the best means of carrying out his expressed desire. The Cawthron centenary lecture, "The Achievements of the Cawthron Institute", delivered on October 9 by Prof T H. Easterfield on his retirement from the directorship of the Institute, formed a fitting epilogue to the first Cawthron lecture, "The Aims and Ideals of the Cawthron Institute", given by him in 1917.

Beginning with the early work of the Institute, Prof Easterfield said that one of the first problems to be attacked was the improvement of the fruit industry A soil survey of the Nelson province was initiated, and the distribution and special characteristics of the soils studied with particular reference to fruit growing The information thus gained led to recommendations with regard to soil treatment and cover cropping without which many orchardists would have been obliged to abandon their crops. Biological problems such as bitter-pit, black spot, woolly aphis and codlin moth were investigated concurrently. An insect, *Aphelinus mali*, was imported in 1920 for the control of woolly aphis and induced to breed in New Zealand Its remarkable success is evidenced by the fact that it is no longer necessary to spray trees which formerly had suffered heavily Such parasitic control is being extended with promising results to other insect and plant pests including the blowfly, which attacks lambs, and the piri-piri, a burr-producing plant which seriously reduces the commercial value of wool fleece Much useful work has been done in controlling fungus diseases of fruit and flowers In the work on black spot, the main fungal disease of pip fruit, it has been found that infection can be controlled by spraying at a period, varying with the season, when ascospores are just about to be ejected by the fallen leaves of the previous year

Prof Easterfield gave further instances of researches which have resulted in outstanding increases in the production of fruit and other important crops, notably the control of brown rot in peaches, the improved fertilising of raspberries, the selection of soils for tobacco and lucerne, the steam sterilisation of tomato soils, and the cultivation treatment of barley Discussing the extensive work on the mineral content of pastures, he said that the data so far recorded promise to have a very marked effect on the agricultural practice of the future, and emphasised the importance of supplementary fodder production for stock Studies of stock ailments such as bush-sickness and xanthin (urinary) calculi of sheep have also yielded conclusive evidence indicating the means of controlling them The first, due to nutritional deficiency of iron, has been shown to be due to lack of soluble forms of iron in the soil rather than in the pasture, stock appear to derive much of the iron they need by ingestion of the soil itself It has also been shown that xanthin calculi can be avoided by the encouragement of English grasses and clovers, by suitable top-dressing, and by the supply of supplementary feeds.

Among other examples of the practical value of the work of the Institute, Prof. Easterfield referred to the economic importance of the investigations carried out on the reclamation of the extensive pakihi lands occurring chiefly in the more populated mining districts Field plot studies have shown that it is possible to bring the land, supporting only fern and rush in its natural state, into a condition suitable for dairy farming at a cost as low as £6 per acre

The Japanese Seismic Sea-waves of March 3, 1933

THOUGH we may have to wait some time for the complete reports on the great Japanese earthquake of March 3, 1933, some valuable papers have recently been published*, of which an abstract is here given The earthquake occurred at about 2 32 a m, Jap Stand Time, on March 3 (5 32 p m on March 2, G M T). From the records at stations connected with the Earthquake Research Institute, Prof Ishimoto finds the epicentre to be in lat 38 2° N, long 144 0° E., while the observations at Tokyo, according to Prof. Imamura, place it in lat 38 5° N., long. 143 3° E The latter point is represented by the more southerly of the two crosses in the accompanying map (Fig 1), the other being the epicentre of the great earthquake of June 15, 1896. The dotted lines on the map are isobaths in thousands of metres, and the two points, which are about fifty miles apart, both lie near the isobath of 4000 metres or about $2\frac{1}{2}$ miles, on the northern slope of the Tuscaroora Deep, the depth of which exceeds five miles

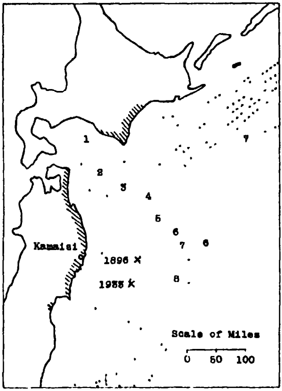

FIG 1 Isobaths of the Japanese earthquake of March 3, 1933

The point given above is that below which the movement of the crust block began It differs slightly, however, from the origin of the great sea-waves. Assuming the velocity of the waves to be $\sqrt{(gh)}$ ft per sec., where h is the depth in feet, Mr. R Takahasi has determined the position of the wave-centre from the times of arrival of the sea-waves at Miyako, Tyôsi and Tukihama, namely, lat. 38 3° N, long 143 6° E

Both points, however, being about a hundred miles from the coast, the shock, though widely felt on land, caused only slight damage along and near the coast After an interval, ranging from 25 to 40 minutes, the great sea-waves swept over the shores shaded on the map, and drowned 3,022 persons, washed away 6,889 houses, besides destroying more than 8,000 boats and other vessels In 1896, the earthquake was less severe than in 1933, but the waves were in most parts higher, and the destruction was far greater, 27,122 lives being lost and 10,617 houses washed away. In Hokkaido, the greatest height of the waves as shown by marks left on trees, posts, slopes, etc, was 15 ft. In the Main Island, it was 15 ft at Kamaisi, the place that suffered most in 1896, but somewhat farther to the south, it rose to 62 ft along the coast at Ryôri Sirahama (and 93 ft inland) and 75 ft. at Hirota Atumari. The waves swept in with such velocity that a motor-boat from Kamaisi, with a speed of 12 miles an hour, could make no headway against them. Across the Pacific, they were recorded by mareographs at Honolulu, San Francisco and Santa Monica.

Mr. K. Musya has made an exhaustive study of the luminous phenomena seen as the waves came in. Among them is reported a strong flash of light that seemed to be emitted from the surface of the sea near the mouth of Kamaisi Bay. Prof. Terada shows that the most probable explanation of the flash is that the turbulence of the water in front of the

* M Ishimoto Preliminary notes on the *tsunami* of March 2, 1933 (G M T), and an outline of the investigations now being made concerning it at the Earthquake Research Institute *Japan J. Astron Geophys*, 11, 1–9, 1933

A Imamura and Z Kawase The Sanriku *tsunami* of 1933, *ibid*, pp. 17–35

T. Terada Luminous phenomena accompanying destructive sea-waves (*tsunami*). *Proc. Imp Acad*, Tokyo, 9, 367–369, 1933

Notes on the prevention of damage from *tsunami*. Issued by the Imperial Earthquake Council, 1933.

advancing wave excited simultaneous luminosity in a swarm of, say, *Noctiluca miliaris*.

The coasts of Sanriku contain many V-shaped indentations facing the Tuscaroora Deep, and they have suffered so often from the sea-waves from the northern slope of the Deep, especially in 869, 1611 and 1896, that the Imperial Earthquake Investigation Council has issued a volume of notes on the prevention of damage from *tunami*. The main suggestion is the removal of coast villages to elevated ground, but, if this should be impossible, the construction of defence works, such as sea-walls and breakwaters, or groves of trees, and the provision of avenues of escape and *tunami* warnings. C D.

University and Educational Intelligence

LONDON.—A special committee has been appointed to report fully as a matter of University policy on the amount and nature of technological study at present carried on in the University, and as to the desirability of instituting a new Faculty of Applied Science or Technology.

IT is announced that Miss Ethel Strudwick has been appointed a trustee of the London Museum Miss Strudwick is high mistress of St Paul's Girls' School, and her appointment is intended to associate schools with the museum.

A COURSE of nine lectures on cathode ray oscillographs will be given at East London College, Mile End Road, London, E 1, on Mondays at 5 30, commencing on January 22 The first lecture, entitled "Cathode Rays and their Use in Electrical Engineering", will be delivered by Prof J. T MacGregor-Morris; lectures 2–5, entitled "Low Voltage Oscillographs", by Mr. L. H. Bedford; and lectures 6–9, entitled "High Voltage Oscillographs", by Prof. G I Finch. Admission will be free, without ticket

ON the place of biology in education hangs the efficiency of efforts to popularise appreciation of the laws of health In this belief, the British Social Hygiene Council organised a year ago a conference on the subject, and set up in March last, as an outcome of the conference, an Educational Advisory Board In a leaflet recently issued, the objects of the Board, its composition and committees and the services it offers are set forth in detail It aims at promoting the teaching of biological sciences in all kinds of educational institutions, at securing adequate recognition for biology as a general and as a specialist subject by examining bodies, and at giving guidance in the production of textbooks and teaching material Its chairman is Dr. W. W. Vaughan, formerly headmaster of Rugby, and among its members are representatives of the Board of Education and the Scottish Education Department, of most of the universities of Great Britain, of several examination boards, of many associations of members of the teaching profession and of local education authorities. One of the standing committees concerns itself with the teaching of biology in outlying parts of the British Empire, especially colonies and protectorates and mandated territories under British rule. The Board offers a variety of services including recommendation of books, advice regarding syllabuses and information about current research in methods of teaching.

Science News a Century Ago

Death of M. Hachette

On January 16, 1834, the eminent French mathematician and engineer, Jean-Nicolas-Pierre Hachette, died in Paris at the age of sixty-four years. Born in Mézières on May 6, 1769, he was the son of a bookseller and was educated at Charleville and Rheims At the age of nineteen he became a draughtsman in the military engineering school at Mézières, and four years later was made a professor of hydrography at Collioure. His mathematical writings having brought him to the notice of Monge, who then held the post of Minister of Marine in the Revolutionary Government, Hachette in 1793 was made a deputy-professor at Mézières, and the following year at the battle of Fleurus on June 26, 1794, he assisted Guyton de Morveau in the experiment of using a balloon for military observations A few months later, after the fall of Robespierre, he assisted Monge and Guyton de Morveau in founding the École des Travaux Publiques, renamed in 1795 the École Polytechnique, and was given the chair of descriptive geometry. In 1798 with Berthollet, Monge, Fourier, Jomard and other savants he accompanied Napoleon to Egypt. Once again in France, he resumed his lectures at the École Polytechnique, having among his students Arago, Poisson and Fresnel At the restoration in 1816, like Monge he was deprived of his chair and twice the Government refused to allow his election to the Academy of Sciences, which he did not enter until the Revolution of 1830 His writings comprise an admirable series of works on descriptive geometry, many reports on mathematical and physical subjects and memoirs on machines Though his name is connected with no great discovery, his services were of great importance to constructors of machinery, and as a man he was respected for his amiability and uprightness.

Sir John Herschel at the Cape

After his father's death in 1822, Sir John Herschel lived at Slough with his mother, continuing the survey of the northern heavens with the 20 ft. telescope he had made under his father's directions. His 'sweeps' resulted in a catalogue of 2,307 nebulæ of which 525 were new discoveries, presented to the Royal Society in 1833. "Strongly invited," as he himself said, "by the peculiar interest of the subject, and the wonderful nature of the objects which presented themselves," he resolved to attempt the completion of the survey of the southern hemisphere, and on November 13, 1833, embarked with his wife and family in the *Mount Stewart Elphinstone*, and after a prosperous voyage landed at the Cape on January 16, 1834, about ten days after Maclear, the successor of Henderson as H.M. Astronomer "Choosing as the scene of his observations a rural spot under the shelter of Table Mountain, he began regular 'sweeping' on the 5th of March The site of his great reflector is now marked by an obelisk, and the name of Feldhausen has become memorable in the history of science; for the four years' work done there may truly be said to open the chapters of our knowledge as regards the southern skies" (Clerke).

Herschel's work at the Cape led to an extraordinary hoax which had a remarkable sequel. On the staff of the newly-founded New York *Sun* was the reporter Richard Adams Locke Locke contributed to the *Sun* a series of articles stated to be based on Herschel's discoveries with a giant telescope which enabled him "to study even the entymology of the moon in case she contained insects upon her surface". The fake, of course, was later on exposed, but was regarded with amusement. It had helped to establish the *Sun*, which achieved the largest circulation of any daily in the world, 19,360 copies as against the 17,000 of the London *Times*, and led to the birth of cheap newspapers "We are indebted," said Edgar Allen Poe, "to the genius of Mr Locke for one of the most important steps ever taken in the pathway of human progress" (see *British Weekly*, Jan 16, 1918)

Examination of Mummies

A mummy was opened at the College of Surgeons on January 16 by T J Pettigrew, F R S , in the theatre of the College, before a very crowded audience, consisting not only of members of the College, but also scientific men generally who had been invited by advertisements It was stated that the mummy was the property of the College, and had been in its museum since 1820, brought from Thebes by Henderson Mr Pettigrew said that a mummy opened at the Leeds Philosophical Society was covered an inch thick with an aromatic powder In concluding his discourse, Mr Pettigrew expressed his pleasure that this antiquity had proved to be a male subject, as he had predicted, and did not therefore bring into question his reading of the inscriptions

Quantity of Electricity to Decompose a Grain of Water

Faraday's experiments on the decomposition of compound bodies by electrolysis, described in the Seventh Series of the "Experimental Researches in Electricity", led him to speculate as to the "quantity of electricity associated with the particles or atoms of matter", and his wonder was excited by the "enormous electric power of each particle or atom" which his measurements showed "What an enormous quantity of electricity therefore", he says, "is required for the decomposition of a single grain of water" He compares the quantity of "voltaic" electricity required for the purpose, measured electro chemically, with that of "common" electricity from the frictional machine, and finds that "the proportion is so high that I am almost afraid to mention it" This experiment was recorded on January 17, 1834, in the Diary ("Faraday's Diary" Vol 2, p 214) The "battery" was a little voltaic arrangement of zinc and platinum wires dipping into sulphuric acid .

"Now in this form of battery 1 gr of water require solution of 3 6 grains of zinc—and as 6 8 gr dissolved in 7 days, 3 6 would require 3 7 days ; but if a wire 5 inches long required 3·7 days to loose 3 6 grs , one only ⅛ of an inch in length but of the same diameter would require 29 6 days for solution of same weight, if constant action could be sustained Now the comparitive battery required 0 0533 of a minute to equal one charge of Leyden battery, but 29 6 days divided by 0 0533 of a minute gives very nearly 800,000. So that from this calculation the electricity required to decompose a single grain of water is about equal to that of 800,000 charges of the Leyden battery, any one of which would kill a cat or dog."

Societies and Academies

LONDON

Physical Society, Dec. 15 G. I FINCH and A G. QUARRELL : Crystal-structure and orientation in zinc oxide films. A new type of electron-diffraction camera is described incorporating means for greatly increasing the accuracy hitherto obtainable in electron-diffraction analysis Partially and completely oxidised zinc films have been examined by transmission. The normal type of zinc oxide is formed by the oxidation of zinc via a zinc oxide which is basally pseudomorphic with the zinc. The corrosion-resisting properties of zinc appear to be due, in the main, to a protective coating of such pseudomorphic zinc oxide A. O RANKINE . Note on the behaviour of the Eötvös gravity balance in fluctuating gravitational fields Attention is directed to the semi-diurnal variation of gravity at a point on the earth's surface, due to lunar attraction and recently measured by Loomis. This temporal variation of g is much larger than the spatial differences measured by the Eötvos gravity balance, but it produces no effect on the balance. This constitutes an experimental proof of the power of the Eötvös instrument to discriminate between space and time changes of terrestrial gravitation ALLAN FERGUSON and J. T. MILLER The temperature variation of the orthobaric density of unassociated liquids. A formula connecting the orthobaric density of a liquid and its temperature is developed in the form $\rho = 2\rho_c[A\ (1-m)^{0\cdot 3}+(1-\frac{1}{2}m)]$, where m is reduced temperature and A is a constant which varies slightly from liquid to liquid, and may be taken to have a mean value 0 911 The formula is a long-range one, and has been tested for thirty pure organic substances It has been applied to the evaluation of expansion coefficients and to show the manner in which free and total molecular surface energy vary with temperature L C MARTIN : The *theory of the microscope* (2) A discussion of the effects in dark-ground illumination when the image of the source of light is projected into the object plane by an illuminator of the symmetrical type The treatment is two-dimensional. The conditions necessary for the formation of genuine and spurious images are investigated, and it is shown that the Abbe principle is theoretically valid in the cases considered A short practical investigation with Grayson's rulings supports the theoretical conclusions, but indicates the desirability of closer examination of the causes of misleading interference phenomena G GRIME Measurement of impact stresses in concrete A quartz piezo-electric gauge, using a cathode-ray oscillograph for recording, has been developed to measure impact stresses in concrete It is being employed to study the stresses in driven reinforced-concrete piles.

PARIS

Academy of Sciences, November 27 (*C.R.*, 197, 1257–1368) EMILE BOREL : Studies on the probability of series of rainy days or of fine weather. The analysis of 50 years' data, taken at Paris between October 1 and January 31, shows that given a run of either fine or wet days, there is a tendency towards persistence of the run (see also NATURE 132, 864, Dec 2, 1933) GEORGES CLAUDE : New progress in lighting by luminescence. The light emitted by neon-mercury lamps is known to be deficient in the blue region. The use of a coating of zinc sulphide has been suggested and the present communication describes a practical method for forming and fixing this coating Increased efficiency results, the tubes thus treated requiring 0 3 watts per candle instead of 0 4 in the usual type **Fred. Swarts**: The catalytic hydrogenation of trifluoracetic anhydride: trifluoralcohol Trifluoracetic anhydride is reduced by hydrogen under pressure (40–50 atmospheres) in the presence of platinum black, the reaction products being trifluorethyl trifluoracetate, trifluorethyl alcohol, trifluoracetic acid and trifluorethane. The methods of separation of these substances, together with their physical and chemical properties, are described **M Gignoux, L Moret** and **D Schneegans**. The geological structure of the gap of L'Argentière to the south of Briançon (Hautes-Alpes) **Maurice Fréchet** The coefficient known as the correlation coefficient **I Pétrowsky** The topology of real and algebraic plane curves **Gaston Vergnères** The unicity of the *minimum* distance from a point to an ensemble **Georges Bouligand** C M parallelism and parallelism in the classical sense **Bertrand Gambier**. Lines of connexion of surfaces. geodesic lines, umbilical lines, lines of curvature **Georges Kurepa** General separable spaces **Rosenblatt**· The application of Picard's method of approximations to the study of certain partial differential equations with real and multiple characteristics **N Adamoff** Some properties of the integrals of an equation of the second order with periodic coefficients. **Paul Flamant** Convergence and compacity in classes of (D) quasi-analytical functions **M Mursi** The values of the modulus of $\sigma(z)$ at infinity **Alex Véronnet** The complete evolution of a heterogeneous mass in rotation The impossibility of a division into two The figure of a heterogeneous mass in rotation, although not rigorously ellipsoidal, is nearly ellipsoidal Owing to the perfect continuity of the figures of equilibrium, it is impossible to explain the formation of double stars **Jacques van Mieghem** Dirac's system of equations and the equation of Jacobi **Albert Toussaint**· The corrections to be applied to the aerodynamical characteristics of a supporting wing, under experiment in a wind tunnel with rectangular air stream semi-guided by lateral walls, parallel to the spread of the wing **Ch Sadron** A new optical method of exploring a field of bidimensional velocities The method is based on the work of Maxwell regarding the double refraction presented by liquids in motion in the regions where the velocity gradient differs from zero With suitable precautions, the method proposed can be used to measure the velocity gradient up to a distance of the order of 0 1 mm. from the wall. **Max Serruys** Recording piezometric effects resulting from knocking in internal combustion motors. Four reproductions of records are given, one in normal working without knocking, three showing various conditions of detonation They show that detonation is produced at the end of the combustion and corresponds to the combustion of only a small proportion of the mixture The velocity of propagation of the detonating waves appears to be about 500 metres per second for normal compression (5 5 : 1). **Conrad Kilian** and **J Petit-Lagrange**· The probable course of the Tafassasset oued below the wells of In-Afellallah **J Tilho** Remarks on the preceding communication **Francis Perrin**: The materialisation of electrons during the collision of two electrons Various processes of annihilation of positive electrons **J. Géhéniau**: The L de Broglie waves in any gravific and electromagnetic field **A Guillet**. The stabilisation of the frequency n of the alternating current supplying a system. **L. Néel** The fluctuations of the molecular field and the magnetic equation of state of nickel **N Thon** Remarks on the theory of supertension of metals **Mme Branca Edmée Marques**. The fractional crystallisation of radiferous barium chloride **Yeu Ki Heng**. The influence of neutral salts on the rotatory power of α-phenylethylamine chlorhydrate **Mme. A Dobry** and **J. Duclaux** The viscosity of cellulose solutions It was suggested by J Duclaux and E. Wollman that the value of k in the Arrhenius formula is, as a first approximation, independent of the solvent, but this has been contested by other workers Calculating the coefficient k of Arrhenius to infinitely small concentration (k_0) it is now shown that the variations are small, the extreme values of k_0 for eleven solvents being 126 and 143 **Léon Guillet, *Jr.***. The modulus of elasticity of the α bronzes in the annealed condition The decrease in Young's modulus with increasing proportions of tin in the alloy follows a linear law to the first approximation. **Pierre Jolibois** and **Georges Fouretier** The crystalline analysis of unstable precipitates. **Mlle M L Josien** Contribution to the study of iodometric determinations **P Carré** and **D Libermann** The alkyl and aryl bromosulphites By the interaction of thionyl bromide on alkyl or aryl sulphites, bromosulphites can be prepared possessing the general formula RO SO Br **Mlle M Darmon** The preparation of phenylacetylcarbinol and of some of its other oxides **Henri Wahl** The chlorine derivatives of paraxylene. **Léon Enderlin**· Researches on the chemistry of the rubenes A colourless hydrocarbon with violet fluorescence derived from diphenylditolylrubene **Duquénois** The conditions of fixation of $HSbO_2$ by some aromatic monoacid monoalcohols β-Phenyl-α-lactic acid forms the best crystallised emetics and these are also less readily hydrolysed. Their stability is comparable with that of the tartaric emetics **Frèrejacque** The oxidation of uric acid in the presence of glycocoll By oxidation in a special manner described, salts of isoallantoylaminoacetic acid were obtained. **A Dauvillier**. The origin of atmospheric ozone Researches made at Scoresby Sound during the Polar Year **P Idrac**· The study of the internal movements of cloud masses by accelerated kinematography **L Herman** The absorption of ultra-violet radiations in the lower atmosphere **A Demolon** and **A Dunez** Bacteriophage and fatigue in soils under lucerne **Mlle M. L Verrier**. Researches on the visual field of the vertebrates. Determination of the field of vision of *Scorpæna scrofa* **G. Petit** Remarks suggested by the discovery of the skull of a cat in the sub-fossil deposits of Madagascar. The presence of this skull is in agreement with the hypothesis of human immigration into Madagascar from Africa at a very remote date **P Lassablière** and **A. Peycelon**: The comparative action of raw meat and of calves' liver on the general nutrition Raw meat proved to be superior to calves' liver in the general nutrition of dogs **Louis Baudin** Diurnal variations of the blood in fishes **Raymond-Hamet** Does oxyacanthine, the alkaloid of *Berberis vulgaris*, possess a sympathicolytic action ? **J. Risbec**: An enemy of *Brontispa froggatti* at the New Hebrides **E Brumpt**: Experimental fatal ascending paralysis of the dog due to the bite of the Australian tic *Ixodes holocyclus*. G. Sydney

Linnean Society of New South Wales, Sept. 27 W W. Froggatt The Coccidæ of the casuarinas. Twenty-eight species of the coccid fauna of the casuarinas are described or noted, five of the species being new. The new species belong to the genera *Gymnaspis* (1), *Eriococcus* (3) and *Pseudaripersia* (1). One genus is also described as new. E. C. Chisholm: Useful Coccinellidæ found on the Comboyne Plateau. Notes are given on eight species of Coccinellidæ which are of economic importance on the Comboyne Plateau Seven of these species are insectivorous and the eighth is vegetarian Ida A. Brown: The geology of the south coast of New South Wales, with special reference to the origin and relationships of the igneous rocks. The tectonic history from Cambrian (?) to post-Tertiary times, considered in relation to the building of south-eastern Australia, indicates that the south coast district was portion of a mobile borderland-massif until the close of the Middle Devonian, when it finally became a portion of the continental massif of Australia The history of igneous activity is closely related to the tectonic history, and, viewed broadly, supports Harker's generalisation of the association of sub-alkaline and alkaline intrusions with orogenic and epeirogenic earth movements respectively. An ultimately comagmatic origin for all the igneous rocks is suggested.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public*]

Monday, January 15

Victoria Institute, at 4 30—(at the Central Hall, Westminster)—Capt B Acworth "Bird Flight and its Bearing on Evolution"

Royal College of Surgeons, at 5—Prof W E Le Gros Clarke "The Evolutionary Origin of Primates" (succeeding lecture on January 17)

Royal Geographical Society, at 5—Miss Cecilia Goodenough "Homesteading in North-Western Canada".

Tuesday, January 16

Eugenics Society, at 5 15—(at the Linnean Society, Burlington House, London, W 1)—"Safeguards in Eugenic Sterilisation"; speakers, Drs R Langdon-Down, E Mapother and C P Blocker *

King's College, London, at 5 30—Prof Felix Krueger "Work, Machines and Man" (succeeding lectures on January 18 and 19) *

Wednesday, January 17

Royal Microscopical Society, at 5 30—(Annual Meeting to be held in the B M A House, Tavistock Square, London, W C 1)—Conrad Beck "Some Recent Advances in Microscopy" (Presidential Address).

Television Society, at 7—(at University College, London, W C 1)—G Parr and T W Price "The Application of the Cathode Ray Tube to Television"

Royal Meteorological Society, at 7 40—(Annual General Meeting) Presentation of Symons medal to Sir Gilbert Walker

Prof. S. Chapman: "The Gases of the Atmosphere" (Presidential Address)

Royal Society of Arts, at 8.—J. M. Waldram: "Modern Developments in Street Lighting"

Friday, January 19

King's College, London, at 5.30—D. B Hoseason: "Apparatus for Power Factor Correction" (succeeding lectures on January 26 and February 2) *

Industrial Research

PARTICULAR attention is given to the work and position of industrial research associations in the annual report of the Department of Scientific and Industrial Research issued a few days ago The reason for this is that the fund of one million pounds granted by Parliament nearly sixteen years ago for the promotion of industrial research in Great Britain, through research associations, has now been exhausted, and the time has come for the whole subject to be surveyed, as well as for the consideration of a policy for the future When an industry is protected by a tariff, the State should demand in return that the industry is maintained in a condition of progressive efficiency , and this can only be achieved through continued developments of methods and processes Some large industrial concerns are in the position to maintain extensive research departments themselves , but if the existence of these establishments means that the co-operative work of the industrial research associations is left to smaller firms, and that some of the associations have to close down for lack of adequate financial support, the result, from a national point of view, will be unfortunate—to say the least

The Department of Scientific and Industrial Research was formed during the War as the result of a memorial from the Royal Society and other scientific and technical societies to the Government in May 1915 urging that assistance should be afforded "for scientific research for industrial purposes" In response to this appeal, a Committee of Council, presided over by the Lord President of Council, was constituted, with an Advisory Council of scientific men and industrialists The functions of this Council were . (1) To act as scientific advisers to all Government departments concerned with, or interested in, scientific research (2) With the co-operation of scientific societies, to consider the application of science to industry and enlist the interest of manufacturers (3) To advise the Board of Education as to steps which should be taken to increase the supply of workers competent to undertake scientific research

In the year 1917 Parliament placed a sum of one million pounds sterling at the disposal of the Committee of Council for the promotion of industrial research ; and a scheme was drawn up for the establishment of research associations connected with various industries, each of which was to receive for five years a grant on a fifty-fifty basis in aid of its expenses From the first, the guiding principle of the Department of Scientific and Industrial Research has been to induce the industries to do things for themselves rather than to attempt to do scientific work for them In the fifteen years during which the million pound fund was available, five thousand or so firms contributed £1,750,000 to the support of their industrial research associations, and there are nineteen such associations now in existence At present Parliament provides £65,000 a year and industry £170,000 towards the support of these associations Most of the associations have established their own research laboratories, but others have their investigations carried out at the National Physical Laboratory and in universities and similar institutions

The industrial research associations represent, however, only one side of the activities of the Department, which has also established a number of special stations on a large scale for building research, chemical research, food investigation, forest products research, fuel research, radio research, and water pollution research During the past year, seventy-six per cent of the expenditure of the Department has been used for these stations and thirteen per cent in support of industrial research associations

Although the Department has done a great deal to encourage fundamental scientific research in universities and other institutions, and is in close co-operation with the Royal Society, which receives an annual grant from the State in aid of purely scientific investigations, quite properly there has been no attempt to organise such research. Such a proceeding would be repugnant to the best research workers At the same time no expenditure has ever earned such big dividends for industry and for the community as the money spent on pure research One has only to think of such things as the modern electric lamp, the wireless valve and the photoelectric cell—products of pure research on atomic physics—to realise this. Although the majority of new knowledge which springs from fundamental research undoubtedly finds its application in industry, nevertheless the lag between scientific discovery and its use in industry has in the past been far too long.

Leaders of industry are finding that the methods followed by the men of science in approaching their problems can be followed with advantage in tackling many of the problems confronting modern industry The result of this during the last few years has been the organisation of research sections in many of the larger industrial concerns, and the formation of the industrial research associations to serve the interest of industries where the units of production are similar.

One of the best illustrations of the way that science is strengthening the chains of production is that of one of our oldest industries, the wool trade In the first place, wool is not a standardised raw material, many factors such as soil, climate, disease, gland secretions, food and management affect the quality of the wool The influence of all these factors on fibre qualities such as strength, diameter, elasticity and so on, which play an important part in manufacture, are being scientifically investigated Methods of controlling them are being sought with the view of reducing variations in the quality of the raw material. In the second place, the older methods of processing the wool, have, in the case of nearly all our older industries, been worked out without conscious planning The methods of science are therefore being applied in the technical improvement of these processes, and ways are being sought through the application of science for cutting costs and increasing efficiency.

The first of these two aspects of wool research concerns the big wool-growing countries, Australia and South Africa, and the work on these aspects is being carried out in Australia, for example, under the Commonwealth Department of Scientific and Industrial Research The link, however, between that work and inquiries seeking to discover how wool qualities are affected by feeding and by the soil, is the Wool Industries Research Association The Association has suggested that elasticity is directly connected with the sulphur content of the wool fibre. It has been found that sheep obtain sulphur in the form of a protein called 'cystine', and accordingly experiments are in progress overseas on the effect of extra cystine with the object of raising the sulphur content of the wool. Similarly fineness in the wool may be due to deficiency in phosphorus.

The same kind of link between the Empire grower and the manufacturer is maintained by the Shirley Institute, which is the Research Laboratory of the British Cotton Industry Research Association, where there is a staff of more than 200, of whom about 70 are fully qualified scientific investigators. The income of the Association is well over £50,000 a year, four-fifths of which is subscribed by the trade and the remainder by the Department of Scientific and Industrial Research Eighty per cent of the cotton firms in the country engaged in all parts of the industry from spinning to finishing are members of the Association The work of the Association has resulted in producing a large number of small improvements which altogether reach a substantial total. It has been calculated that a saving of something like £300,000 a year is being effected in Lancashire by the research carried out by the Research Association This gives a return of about 500 per cent on the money invested in research

One of the most productive researches ever carried out under the auspices of the Department depended mainly on the measurement of the conductivity of heat of soils and insulating materials. Cables distributing electric power in populated areas are, of course, put underground The electric currents naturally heat them, and the amount of current they can carry depends on the rate at which this heat is conducted away Accurate measurements on this point, carried out on behalf of the Electrical and Allied Industries Research Association, indicated that the heat conducted away was in most cases greater than had been supposed It was therefore shown that existing cables could be further loaded with safety to an extent representing a capital value in cables of £4,000,000

Related to this subject are investigations into the deterioration of lead sheath cables arranged by the Non-Ferrous Metals Research Association and carried out at the Research Department, Woolwich Lead sheath cables, though generally excellent in service, were found to suffer failures on board ship, in submarine and aerial cables where movements by tide or wind could occur, in railway service of bridges, in tunnels and, in fact, in all positions where they suffer exceptional vibration The breakdowns were very troublesome as the failure started from the inner part of the sheath and could not be seen until a complete breakdown of the sheath took place The cause was investigated by the Research Association, which was able to produce two new ternary alloys of lead containing lead-cadmium-antimony and lead-cadmium-tin which have a fatigue resistance three and a half times as great as the ordinary pure lead. These alloys have solved the problem with regard to the deterioration of lead cable sheathing. It may be remarked that 80,000 tons per annum are used in Great Britain for this purpose and in the United States one company alone uses 75,000 tons of lead for the sheathing of telephone cables. The new alloy is used on the new Post Office submarine telephone cable to France. In addition to this better fatigue resistance, the new alloy is also at least fifty per cent stronger than pure lead in other respects, and it is therefore likely that it will have a great future for improved water pipes

These examples selected from recent reports illustrate the bearing of scientific research upon industrial progress and commercial profits It would be easy to advance many others to show that scientific research should be looked upon not as a last resource but as an essential part in the business of production It is now generally recognised that the initial advantages which Great Britain secured through her island position, her natural resources, and the technical skill of her workers, are no longer sufficient in themselves to enable our manufacturers to withstand the organised and scientific rivalry of competing countries The full utilisation of the results of scientific research, and the substitution of scientific for empirical methods can, however, only be secured as a result of confidence in the scientific workers engaged in the study of the problems concerned and of acquaintance with the existence and value of this large body of scientific knowledge and research

Although scientific methods are much more widely used in almost all our industries than even a few years ago, there is not yet a general disposition to accept an adequate and sustained programme of research as a fixed charge, comparable with insurance, depreciation, obsolescence, etc, without which no industry can progress, if indeed it can survive Science, whether in its broadest aspect or its narrow technical sense, will not occupy its proper place in industry until the industrialist is prepared not merely to admit its possibilities and accept its occasional assistance but also to incorporate it as part of his industrial practice Such incorporation involves not merely the support of research work, whether conducted in his own laboratories or outside, or in co-operation with other firms, but also continuous contact with research in matters of interest to his industry, wherever that research is prosecuted.

With such convincing records as those mentioned in the report of the Department, of the financial advantage and public benefit derived from scientific research, particularly in the province of electrical engineering, it would seem to be unnecessary to urge that electrical manufacturers and supply companies might reasonably be expected to devote a fraction of one per cent of their profits to research, whether in university laboratories or by co-operative effort Leaving purely scientific investigations out of consideration, there are many technical problems awaiting solution, and great savings and economies may be confidently anticipated from systematic research into them, yet the funds provided to the British Electrical and Allied Industries Research Association for such work are a very poor return for benefits received or belief in favours to come The annual revenue of the electric supply authorities in Great Britain is about £45,000,000, and so far their annual contribution to the funds of the Association has only reached about £5,000, though they are benefiting by research done or nearing completion to the extent of a sum approaching £1,000,000 per annum If the public attention given to the recent report of the Department of Scientific and Industrial Research should lead to a wider understanding and more generous recognition of both scientific and industrial research from manufacturers and corporations who profit by the results, it will have achieved a most useful national purpose

Numbers and Numerology

Numerology By Prof E T Bell Pp vii + 187 (Baltimore, Md The Williams and Wilkins Co , London Baillière, Tindall and Cox, 1933) 11s 6d

"EVERYTHING is Number !" Thus spake the son of Mnesarchus Ever since these words were uttered, not only have philosophers vied with each other to find a correct interpretation of them, but also the world has turned its back to the fact-finding approach to human affairs and still enjoys the rhetorical approach of numerology Pythagoras was thus the founder of esoterism and arithmosophy as well as of science and philosophy If the number of followers of any particular doctrine are to be taken as a criterion of its value, then esoterism and arithmosophy may well be given the palm

The predominance of number in the world of appearance is obvious Ancient religions and ancient philosophies recognise a quantitative order in the universe, whatever be their conceptions about its origin The rhythm of life, the rhythm of Nature and the rhythm of the heavens have always appealed to the imagination of man Number and proportion, its subtler aspect, dominate the practical arts of man Without number, there would be no commerce, no architecture, no medicine, no religious cults, and none of the crafts appearing between these landmarks of human interests This profound truth must have been revealed to Pythagoras by the sages of the East with whom he came into contact, and was probed by his own observations and meditations For example, his exaltation in submitting the imponderable vibrations of sound to the law of number, inspired him with his famous doctrine of the harmony of the spheres, when he dogmatically imposed certain numerical proportions between the celestial bodies and their movements It is this Pythagorean spirit which Plato inherited, as is shown in the "Timæus", where he builds up the universe by means of numerical proportions and geometrical figures, a process which culminates in the construction of the five regular solids Moreover, we believe it is not far from the truth to assume that Euclid himself had a Pythagorean vision before him when he wrote his everlasting "Elements" It is significant to observe that his thirteen books end with the construction of the regular solids, as if their author were not interested in the other types of curves and solids already known in his time, once he had given to the world the rational steps leading to the understanding of the wonderful figures with which Plato had created the soul and the universe

This spirit, dormant during the Middle Ages, which were more interested in ethical numerology, becomes supreme again during the Renaissance The mathematisation of astronomy by Copernicus and Kepler, and the foundation of modern mechanics by Galileo on the firm ground of number, were in the best Pythagorean tradition So also was the establishment of analytical geometry by Descartes, a new science which may be considered as a refined form of the arithmetical geometry of Pythagoras Again, the invention of the calculus by Newton and Leibniz gave the man of science new tools for combining his mathematical picture of the universe Ever since, not only have astronomy, physics and chemistry come more and more under the influence of the law of number, but also biology, psychology and sociology Indeed, the most comprehensive thought ever conceived by man is short the cosmos is isomorphic with pure mathematics , an obvious generalisation of the old Pythagorean saying that everything is number At present, we do not know whether it is a great though simple truth or whether it is just nonsense. But we cannot turn our backs on it, though theories are brought forward and discarded with disconcerting speed. In this respect, one may quote the case of Lord Kelvin, who endeavoured to paint one grand inclusive picture of the physical universe which would tell the whole story for ever, the only occasion when he shocked his followers was towards the end of his life, when he summed up his long search by describing it as a failure Yet the same spirit pervades the younger generation, with the difference that instead of trying to construct dynamical models of the universe, they content themselves with purely mathematical maps If a set of differential equations correctly describes the electromagnetic field, why look further? So we are told by Sir James Jeans that God himself is a pure mathematician

If men of science profess such a divine consideration for mathematics, why not allow other types of number-worshippers to discover some numerical relations in the world of ethics and religion? The Pythagoreans maintained that virtue, as well as health, is a harmony obeying certain numerical proportions Justice is also a reciprocal proportion, and friendship is a relation of equality, a belief illustrated by the 'amiable numbers' which are such that each is equal to the sum of the aliquot parts of the other It is considerations of this kind which inspired the systematic researches of cabbalism, occultism and onomantic astrology We ought not to laugh at such beliefs even to-day, more people believe in lucky and unlucky numbers than in the mathematical expression of the external world

The belief that mathematics can explain everything seems to be due to the fact that it has always been considered as the simplest and strongest manifestation of reason So that, if the world is rational, then by studying mathematics in itself, the intellect penetrates more and more into the essence of things. This faith in the power of mathematics has been increased of late, with the growing assimilation of mathematics to logic But then, how can one explain the reason of so many failures in science and of the general inconclusiveness of numerology? The difficulties in both cases are similar to those which account for the failure of primitive Pythagorism. In the simple figure of a square, the Master himself could not find a common measure, a number, between its side and its diagonal If everything is number, how then can we explain the impossibility of finding a number expressing the relation between these two lines? No wonder the discovery of these 'irrationals' was kept secret in the inner ring of the Italic school, and their revelation cast doubts on the leadership of the Master. Thus number which caused the greatness of the Pythagorean order, also caused its breakdown The efforts of the later mathematicians, and of Plato himself, tended to integrate the 'irrationals' into a comprehensive system of thought Thus we soon had a theory of the 'irrational quantities' established by Theodorus of Cyrene, a theory of 'negative quantities' added by the Renaissance, and the 'infinitesimal quantities' invented by the seventeenth century in its endeavour to follow Nature as closely as possible. Still unable to exhaust Nature numerically, the nineteenth century thought of 'imaginary quantities', and we have had since such extraordinary conceptions as the 'ideal numbers' and the 'transfinite numbers', to which even mathematicians take exception Whence Kronecker's aphorism "God has created the integers, and everything else is human"

In this race towards the understanding of Nature, of man, of the universe as a whole, can we hope that number will overtake all the difficulties lying on its path? We doubt it; for numbers cannot identify themselves with human thought and human will, which give them meaning and practical application On the other hand, however true may be Leibniz's aphorism "Dum Deus calculat fit mundus", we cannot be so vain as to pretend that the mathematical mind of God and the mathematical mind of man are identical. That is why one is forced to admit, in the universe, the existence of an irrational element, the existence of pure qualities, which are as yet beyond any mathematical expression, not to mention, of course, the impossibility of expressing mathematically existence itself

Such and similar thoughts are suggested by the reading of Prof. Bell's interesting monograph on "Numerology", in which, without apparently taking sides, he is rather sceptical as to the value of the real claims of numerologists. The amusing stories and examples he quotes, as for example, the 'beasting' of people through the correspondence of their names with numbers, would naturally appear, to an orthodox mathematician, as added arguments in favour of that scepticism.

THOMAS GREENWOOD

Physiological Balance in the Body

The Wisdom of the Body By Prof. Walter B Cannon Pp 312. (London Kegan Paul and Co, Ltd, 1932) 12*s* 6*d* net

BOTH because of the vivid interest of its subject matter and also the simple and clear way in which it is written, this recent book of Prof Cannon should make a ready appeal to a wide circle of the general public as well as to students of the biological sciences It is the fourth of a series of volumes giving the conclusions of the researches he and his colleagues have been carrying out over a period of more than thirty years The first of these, published in 1911, was concerned with the mechanical factors of digestion, but it included also chapters on the nervous control of the digestive process, and the effect of emotional states upon it The second work (1915) was his well-known "Bodily Changes in Pain, Hunger, Fear, and Rage", which stressed the importance of adrenal secretion in connexion with the many somatic changes that occur in emotional excitement The third, "Traumatic Shock" (1923), dealt with the general functions of the autonomic nervous system, and was mainly a war-case study The present volume carries the same general line of study a step further, treating, as it does, of the relation of the autonomic system to the balance (or, as he terms it, homeostasis) of physiological processes

The main part of the book is devoted to showing how, in the blood, the safeguarding of homeostasis in respect of water, salt, sugar, proteins, fat and calcium is brought about, how an adequate oxygen supply is maintained during states of relative passivity and active endeavour, how acid-alkali neutrality is secured, and how body temperature is kept within normal limits All this may sound technical and uninteresting, in point of fact it makes fascinating reading When one realises that the elements of the human body live in an internal environment the character of which must be maintained in order that they, and it, may live, not only are the mechanisms which secure the constancy of that environment, the 'fluid matrix', of supreme importance, but also our knowledge concerning them is of supreme interest Chapters follow on the natural defences of the organism, the margin of safety in bodily structure and function, the divisions of the nervous system, and the part that the sympathetic-adrenal system has to play in homeostasis.

Prof Cannon is careful to show where he is stating ascertained fact and where making use of conjecture, thus at once attracting the layman by the candour of his science and suggesting fresh fields of experiment to the biological worker.

The volume ends with a summary of the general features of bodily stabilisation, and an epilogue dealing with the relations of biological and social homeostasis. The title of the book, borrowed from the late Prof. Starling's Harveian oration of 1923, aptly and picturesquely describes its content It is science, but it reads like a poem.

Tables of the Planets

Planetary Co-ordinates for the Years 1800–1940 referred to the Equinox of 1950 0. Prepared by H M Nautical Almanac Office Pp xviii+156 (London H M Stationery Office, 1933) 12*s* 6*d*. net

IT is not too much to say that the appearance of this volume will be joyfully welcomed by all astronomers who devote their attention to the calculation of planetary and cometary orbits, taking account of the perturbations by the major planets Of late years the advantage of using rectangular co-ordinates, as in the methods of Encke and Cowell, has been more and more appreciated, first because of their greater simplicity, and secondly because of their adaptability to machine-calculations A further advance towards simplicity and economy in arithmetical work consists in the choice of a standard equinox to which the co-ordinates of planets, etc, are referred so as to cover the needs of two or three decades In this volume, the mean equinox for 1950 0 has been selected The advantages of using a standard equinox had been pointed out by Dr L J Comrie some years ago, and it is satisfactory that a proposal of this kind has now been translated into an accomplished fact

The tables of the planets give the heliocentric longitude and latitude, the radius vector (with its logarithm), the heliocentric rectangular equatorial co-ordinates and the rectangular components of the attraction on the sun, all at intervals of 10 days from 1920 until 1940 and referred to the equinox of 1950 0 In addition, these quantities for Jupiter and Saturn are extended backwards to 1900 and the co-ordinates of Uranus and Neptune to 1903 The ecliptic co-ordinates for Jupiter and Saturn are also given at intervals of

100 days from 1800 to 1900 The latter data will enable computers to connect up earlier apparitions of comets or oppositions of minor planets An innovation, which will commend itself to workers in this field of astronomy, is the expression of angular co-ordinates in the decimal division of the degree

There are fifteen subsidiary tables dealing, *inter alia*, with the mean obliquity, ecliptic and equatorial precessional elements, the reduction of equatorial rectangular co-ordinates from one equinox to another, the reduction of star positions, interpolation coefficients and the general formulæ on which the computation of orbits is based

A fully worked out example—the work of Miss Julie Vinter Hansen of Copenhagen Observatory and Mr D H Sadler of the Nautical Almanac Office—in computing perturbations is given in the introduction In addition to illustrating the methods of computation, it affords a practical comparison of the relative merits of the methods of Encke and Cowell

It should be added that the tables have been prepared under the direction of Dr L J Comrie, superintendent of H M Nautical Almanac Office, who must be congratulated on producing a work of such importance to dynamical astronomers

---

Meteorological Science and Art

The Drama of Weather By Sir Napier Shaw Pp xiv +269 (Cambridge At the University Press, 1933) 7*s* 6*d* net

SIR NAPIER SHAW begins this book with a prologue on "Pageantry in the Sky" in which a vivid idea is given of the beauty and wonder of the pictures formed by clouds. The pairs of stereoscopic pictures are particularly to be commended in that the distance separating them is small enough to permit of their enjoyment without the need of optical equipment

We next have the "Ideas of the Drama Ancient and Modern" and trace the gradual advance through magic, witchcraft and astrology The development has closely resembled that of medicine, with which meteorology was formerly united under the care of the 'medicine man' The two sciences have much in common ; the principles of diagnosis and prognosis are alike and, as the author remarks, in weather "the processes of digestion have their counterpart, but here the analogy becomes a little too intimate". When dealing with the demand for forecasts, which has become far more insistent with the spread of wireless telegraphy, Sir Napier Shaw considers that in forcing the meteorologist to pronounce an opinion which cannot always be correct "the stress of service has hampered the progress of science" But he seems to overlook the enormous stimulus to investigation and the increase of financial provision that are the direct outcome of the demand.

In Chap ii we read of "The Watchers What They See and What They Say" The watchers are the meteorological factors—winds, pressure, etc , some too little known weather toys fascinate us for a time and we learn something of the enormous bulk of the collections of data which form "the book of the play"

The chapter devoted to "The Score" shows how observation can be used to provide "a summary of the action of the play and to suggest leading motives for the sequence of events in the weather's arena" There is an admirable collection of diagrams showing different ways of exhibiting variations both in time and in geographical position Effort is undeniably well spent in effecting pictorial representations which will cause to leap to the eye features which would escape notice when buried in masses of numbers : and the author's ingenuity in this respect is well known. As an example may be taken the method of showing the amounts of seasonal transfer of air over the earth, there being ten million million tons less over the northern hemisphere in July than in January

Chap iv is headed "The Chorus Rhythmic Aspects of the Records", and contains an interesting series of contrasts between the periodic variations of the elements and the occasional freaks produced by external, and apparently capricious, interference Sir Napier rightly points out that most periods have such small amplitudes as to exercise but trivial influences on the rainfall of any particular season but this remark is not applicable to all seasonal relationships, and it seems unduly pessimistic to observe that it may "be best to regard our coefficients as poetic illustrations of the meaning of our facts and not as substitutes for them"

The last chapter and the epilogue deal with the weather map and the history of daily forecasting. We read of the disappointment that followed the introduction of Abercromby's ideas, and of the success of Norwegian methods perhaps the size of the book explains the absence of allusion to

Austrian methods of explaining the associated variations in the upper air in terms of its northern or southern origin

Those who know Sir Napier Shaw's other writings will find fulfilment of their expectations of wealth of imagination, crispness of style, love of paradox and freshness of outlook He has played a big part in the creation of the international organisations on which meteorology largely depends for its practical efficiency, and he has always been a fighter, with much disinclination to sit on the fence, so that he takes pleasure in vigorous strokes rather than in delicate expression of slight differences

The advance of science is in some respects like that of a vessel in misty weather The landmarks are hard to make out until somebody has picked them up, and after this they are obvious accordingly there is great value in a book which stimulates thought Although the present work will be intelligible as well as attractive to the layman with some slight knowledge of physics, its suggestiveness and its style alike recommend it to the specialist as worthy of careful perusal G T W

Short Reviews

Handbuch der Geophysik Herausgegeben von Prof Dr B Gutenberg Band 2, Lief 3 *Die Erdoberflache*, von Erwin Kossinna, *Petrographischer Aufbau der Erdkruste*, von Dr S Rosch, *Chemie der Meteoriten*, von Prof G von Hevesy Pp 869–1119+xv 42 gold marks Band 4, Lief 4 *Die zeitliche Folge der Erdbeben und bebenauslosende Ursachen* Von Prof Dr V Conrad Pp 1007–1202+xii 39 gold marks Band 7, Lief 1 *Das Eis der Erde*, von Prof Dr H Hess, *Seen*, von Prof Dr W Halbfass, *Das unterirdische Wasser*, von Prof Dr W Koehne Pp v+252 42 gold marks (Berlin Gebruder Borntraeger, 1932)

FEW readers, and even few authors, of papers on periodicities in the occurrence of earthquakes have taken the trouble to compare the amplitudes they obtain with those that would be expected to arise from the harmonic analysis of a purely random set of observations Prof Conrad has done a great service in collecting the results and testing them in all cases by means of the Schuster criterion Most of the suggested periodicities turn out to be probably not significant, on the ground that they would be just as striking if the observations were arranged in any other order in time instead of the actual one, Turner's 21-minute period is among these The possible survivors are the diurnal and annual periods, and perhaps a 14-monthly one The curious thing about the first two is that they are conspicuous in felt shocks, but not in instrumental ones This suggests that they may be the result of differences between the conditions of observing by day and by night, but then why should the phase vary conspicuously from place to place? Why should it be opposite in some parts of Japan from others?

There is a regularity in the frequency of aftershocks from a great earthquake, the number per unit time falling off according to a hyperbolic law This suggests a relation with the mechanism of elastic afterworking

The price of 42 gold marks for an unbound part of 252 pages is a poor service both for the authors and the reader. H J

British Wild Flowers By Louis Johnstone First Series 16 plates+16 diagrams Second Series 16 plates+16 diagrams *British Trees* By Barbara Briggs Second Series 16 plates+16 diagrams (London The Lutterworth Press, 1933) 3*s* 6*d* net each set

THE biologist always looks askance at "beautiful coloured plates" of biological material, for, unlike the hand paintings of flowers housed at Kew, scientific accuracy is almost invariably either disregarded or masked in the striving for artistic effect None of these series of coloured plates, however, should be placed in the usual category of coloured diagrams of plant and animal subjects In general, they are very accurate, and though they show little but the identity and general structure of the plants they portray, they are to be highly commended, since all the plants are pictured on a background representing their normal habitat There is little fault to find with accuracy in this connexion, except that few botanists would agree that the usual habitat of the white deadnettle is "ruins and rocks"

In each of the two series of wild flowers, 135 species are represented In the series of trees, each tree occupies one plate The usefulness of all three series is enhanced by a collection of line diagrams accompanying each plate, where details of such diagnostic features as flower, fruit, leaf, winter bud, etc, are given

The plates can be highly recommended, for reference purposes, to teachers of elementary nature study and botany, also, they are so attractively done that they would decorate the classroom, laboratory or museum wall.

Mathematical Facts and Formulæ By A S. Percival Pp v+125 (London, Glasgow and Bombay Blackie and Son, Ltd, 1933) 4*s* 6*d*. net

To fill a notebook with the formulæ that happen to have been of most use to himself and the comments that he has found most illuminating is a pleasant and profitable task to anyone who performs it, but the result cannot have value of a comparable kind to any reader. To say that it is hard to know to whom to recommend Mr Percival's discursive jottings, which range from the multiplication of polynomials to the solution of partial differential equations, is not to deny that some of his remarks were worth making. On the other hand, the teacher who expects a protest against the prevalent inaccuracy in presenting the integral of $1/x$ will be disappointed to find only the usual formula, and inverse circular functions are said to be essentially acute angles.

The one surprising feature of the book is a six-figure table of log $\Gamma(x)$, from 1 to 2 at interval 0·001. There are only two substantial mistakes, and these would be patent in use: against 1·255, for 6854 read 6834, and against 1·529, for 8274 read 8174. Perhaps, however, the first row would puzzle an inexperienced user, and when the seventh digit of the Smithsonian table from which he was extracting was a 5, Mr Percival adopted some rule of thumb instead of looking elsewhere for a closer approximation, and fifty entries are at fault by a unit in the last place for this reason.

Men without Money: the Challenge of Barter and Scrip. By Wayne Weishaar and Wayne W. Parrish. Pp. x+111. (New York and London: G. P. Putnam's Sons, 1933.) 5*s.* net.

THE severity of the economic depression in the United States has led to the introduction of barter on a considerable scale, and this book provides a vivid record of a remarkable movement in which about a million persons are participating. The simplest form described is that in which commodities or services are directly exchanged against each other by farmers, dentists, barbers, shopkeepers, doctors, artisans and labourers. Direct barter, however, is limited, since a double coincidence of wants may be lacking. To meet this difficulty, exchanges have been inaugurated to act as clearing houses. One such exchange, for example, found a farmer in Syracuse who was willing to take shirts and shoes for his grain. This was exchanged with a poultryman for eggs and fowls which in turn were traded with restaurants to provide meals for workers engaged in making shirts for the farmer.

Many of the exchanges issue 'scrip' or tokens which circulate as a kind of local money. Certain municipalities have also issued 'scrip' to the unemployed in return for work on the roads. To prevent debasement, this scrip has to be stamped at every transaction, thus building up a fund for its eventual redemption by the municipality.

Sacraments of Simple Folk. By R. R. Marett. Pp. vii+230. (Oxford: Clarendon Press; London: Oxford University Press, 1933.) 10*s.* net.

IN the second series of his lectures on the Gifford foundation delivered in 1932–33, Dr. Marett studies the function of the sacrament in natural religion, that is, as he understands it, in the religion of primitive peoples. A sacrament is defined as "any rite which by way of sanction or positive blessing invests a natural function with a supernatural authority of its own". This definition is tested in the course of the lectures by the study of particular instances among the diverse activities of savage life. Ritual, instead of a deadening, is shown to be a vitalising force, bringing emotion to the support of reason in promoting right action, these terms in this context, naturally, being used in a relative sense.

It will be seen that Dr. Marett's point of view in his analysis of primitive institutions and their ritualistic accompaniments is both psychological and sociological, while he applies a formula to the behaviour of primitive peoples which is equally applicable to that of more advanced civilisations. This, however, is an aspect of his inquiry to which Dr. Marett makes only incidental reference. It should not, however, be overlooked, lest the broader view of anthropological studies be forgotten.

The Progress of Man: a Short Survey of his Evolution, his Customs and his Works. By A. M. Hocart. Pp. xvi+316. (London: Methuen and Co., Ltd., 1933.) 7*s.* 6*d.* net.

"LIVE man," Mr. Hocart says, "wants to know about his past as a key to his present. The man who does not is dead." He has written what is virtually a survey of the material of anthropological science to satisfy that desire. An enormous amount of ground is covered in a small compass; for he has traced the growth and achievement of man "from the time he can be reckoned as man" down to the present day. Mr. Hocart will have none of the arbitrary divisions between prehistory and history, and between savage and civilised. His treatment of the subject is individual in style and original in method; and be it added, at times provocative. It is not possible to comment here in detail upon the many points upon which his views stimulate thought; but attention must be directed to the emphasis he lays on the psychological and ritualistic element in mechanical invention. His protest against the misuse of 'evolutionary' in the study of technical development is salutary.

Network Synthesis: Synthesis of a Finite Four-Terminal Network from its Prescribed Driving-Point Functions and Transfer Function. By Dr. Charles Mason Gewertz. Pp. vi+257. (London: Baillière, Tindall and Cox, 1933.) 23*s.*

THIS work is an interesting exercise, and its subtitle is accurate. The main title alone, however, is quite misleading, for the reader who goes to this book for a general and comprehensive treatment will find that he must first go elsewhere for the foundations on which the author builds, and in the end he will probably conclude that empiricism is sometimes cheaper than pure reason.

The John Murray Expedition to the Arabian Sea

By LIEUT-COL R B SEYMOUR SEWELL, C I E

THE John Murray Expedition has now completed its first three months' work, during which time the H E M S *Mabahiss* has made four cruises, each of approximately three weeks' duration, namely, (1) down the Red Sea and round the head of the Gulf of Aden between Perim and Aden , (2) around the Gulf of Aden and out into the Indian Ocean to the south-east of Socotra , (3) along the southern and south-eastern coast of Arabia , and (4) up the Gulf of Oman We have thus completed our programme of work across the northern part of the Arabian Sea and have carried out observations at 90 stations, of which 18 were in the Red Sea and the Straits of Bab el Mandeb, 20 in the Gulf of Aden or to the south-east of Socotra, 27 along the coast of Arabia, and 25 in the Gulf of Oman and its approaches Of these stations, 15 have been 'complete' ones, including both physico-chemical and biological observations , at 41, physico-chemical observations only have been made , trawls or dredges have been carried out at 37 , and at 8, observations have been made with the Priestman grab

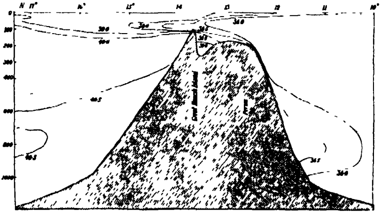

FIG 1 Salinity of the water in the Straits of Bab el Mandeb (*Depths in metres*)

TOPOGRAPHY AND BOTTOM DEPOSITS

Thanks to the installation of the echo-sounding machine, we have been able to carry on an almost continuous survey of the bottom during our four cruises In the Red Sea we were able to confirm the presence of a deep area having a depth of 2,204 metres (1,205 fathoms) in lat 25° 24′ 12″ N , long 36° 12′ 12″ E The bottom in the deeper levels consists largely of a rock, or coarse gravel, containing a high percentage of calcium carbonate, that appears to be forming *in situ*

We have three times traversed the Gulf of Aden along its whole length and have been able to detect the presence of no less than ten definite ridges that run obliquely across the northern and central parts of the Gulf in a north-east to south-west direction, the more westerly ridges showing a tendency to curve westwards We have not yet been able to define the most southerly limits of these ridges, but we hope to do so during our return journey in April next

Along the Arabian coast, throughout the area that we have investigated and extending from Ras Nus, the western headland of Khorya Morya Bay, to Ras al Hadd at the eastern extremity, the coast line is for the most part composed of high vertical, or in some places even overhanging, cliffs, some of which rise to a height of 600–800 ft and are composed of a stratified sandstone alternating with horizontal bands of a harder material or limestone A similar formation is also to be found on the Khorya Morya islands, though some of the steep hills are composed of granite To seaward there is a broad, gently-sloping shelf , but at or near the 50 fathoms level the sea-floor drops with great rapidity and is very irregular, running out in a complicated series of submarine promontories, between which are deep gullies Much of this bottom consists of rock that played havoc with our nets On one occasion we brought up in the dredge from a depth of 1,416 metres (774 fathoms) a half to three quarters of a ton of angular granite blocks of various sizes, without any trace of associated sand or mud, constituting a definite scree slope, and there can be little doubt that the whole coastline is part of a large geological fault

Where not composed of rock, the bottom consists of a brown or green mud, and towards the eastern end in the neighbourhood of Ras al Hadd this green mud smells very strongly of sulphuretted hydrogen Six observations showed that this is present between the depths of 95 metres and 1,253 metres, though most strongly marked at 421–457 metres, the occluded water from a bottom-sample at 421 metres containing as much as 29 39 milligrams of sulphuretted hydrogen per litre This occurrence of sulphuretted hydrogen in the bottom deposit affords a parallel to the condition found in the Black Sea and in some of the enclosed fjords, but its presence along an open seacoast was scarcely to be expected and its cause must at present remain unsolved. A very similar mud bottom, composed of green mud, or in the deepest depths of a grey clay, but not impregnated with sulphuretted hydrogen, is found throughout the whole of the Gulf of Oman and along the coast of Makran and Baluchistan below a depth of about 250 metres.

Between Ras al Hadd and the Indian coast in the neighbourhood of Karachi the echo-sounder has clearly revealed the presence of a submarine ridge that runs westward towards the entrance to the Gulf of Oman more or less parallel to the hill ranges of Baluchistan and Makran. To the south of this ridge and separated from it by a level plain with a fairly constant depth of 1,850 fathoms (3,383 metres) lies a second ridge that runs towards the south-west, and immediately to the south-east of this is a deep gully, bounded in its turn by the edge of a plateau that slopes gradually downwards towards the south-east. The bottom of this gully lies 2,000 fathoms below the sea surface and its general character reminds one strongly of a river bed. Have we here the now submerged bed of the Indus, where it flowed out into the Arabian Sea at a point more to the north of its present mouth or, possibly, the mouth of the great Indo-brahm river, the existence of which was postulated by Pascoe and Pilgrim ?

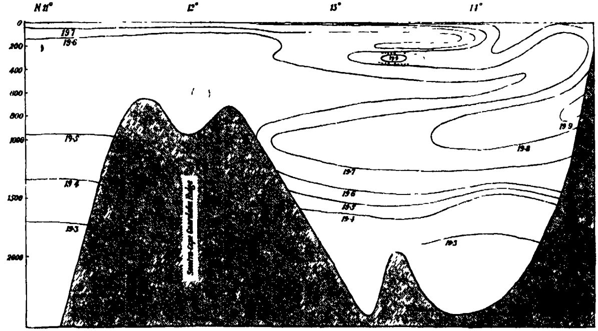

FIG 2. Halogen content of the water of the Socotra current

PHYSICO-CHEMICAL RESULTS

The physico-chemical examination of the sea-water of the Red Sea at all depths between the surface and the bottom indicates that there is in all probability a vertical circulation going on between a depth of 200–300 metres and the bottom, for at a depth of about 400–500 metres the temperature and both the halogen- and oxygen-content of the water are at a minimum and exhibit a clear increase in passing either upwards towards the surface or downwards to the bottom. We hope to carry out further observations on this point during our return journey.

On our way through the Straits of Bab el Mandeb a series of observations was made on the character of the sea-water and the fauna of the shallow channel that connects the Red Sea with the Gulf of Aden. There were indications of at least three different strata of water in the Straits, of which the uppermost was flowing out of the Red Sea, while the second and by far the largest of these water masses was flowing into the basin between the depths of 70 metres and 160 metres. The lowest stratum, namely, that of the bottom water of the Red Sea, was extremely small or even non-existent and scarcely passes over the sill near Great Hanish Island (Fig 1). This condition of the water movements affords a marked contrast to the results obtained by the *Magnaghi* (1924) and the *Ormonde* (1927) in the months of April and May (*vide* Schott[1]). At this latter season of the year it is the outflowing bottom current and not the inflowing current that is the chief characteristic.

A number of serial observations on the sea-water in the Gulf of Aden have shown that there is in the Gulf a very complicated system of deep currents, and this is especially the case at the eastern end, where the "Socotra" current, to which Matthews has directed attention[2], sweeps northwards, partly through the gap between Cape Guardafui and Socotra and partly to the east of the island. A series of five stations running from south to north were made across this part of the Gulf and the results obtained indicate a deep and complicated vertical rotation of the water masses (Fig 2).

At three places along the Arabian coast, lines of stations were run in order to detect, if possible, any upwelling of cold antarctic bottom-water, but so far as our observations go, there was no sign of any such phenomenon On two occasions, off Ras Sukra and Ras Madraka, at the two ends respectively of Sukra Bay, there was a definite fall in the temperature of the surface water by as much as 2 5°, this apparently was not due to the upwelling of deep water, but was probably caused by water upwelling from only moderate depths under the influence of the tidal currents

In the Gulf of Oman (Fig 3), our observations indicate that whereas there is an outflowing current that extends from the surface down to some 30–70 metres and a second similar current extending from 125 metres down to 350 metres on the northern and 500 metres on the southern side of the Gulf, between these two layers there is a stratum of inflowing water that can be traced up the Gulf as far north as Station 71 (lat 25° 35′ 00″ N, long 56° 42′ 18″ E) The bottom water, the upper limit of which lies at a depth of some 350 metres on the northern side and at about 500 metres on the southern side in the vicinity of Muscat, appears to be an offshoot of deep Indian Ocean water that is moving northwards into the Gulf through the gap between Arabia and the Karachi plateau, to which I have already directed attention

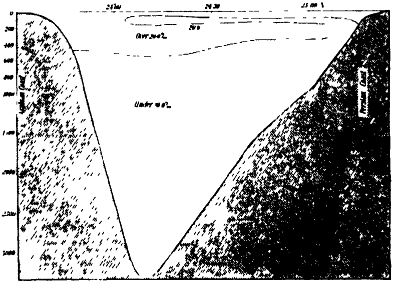

FIG 3 Halogen content of the water across the Gulf of Oman in the region of Muscat

BIOLOGICAL OBSERVATIONS

On the biological side, two areas have proved to be extremely interesting—not because of the richness of their fauna, but, on the contrary, because of its paucity or even complete absence The first is the deep part of the Red Sea During our cruise down this region in September, we carried out several trawls and dredges in depths ranging from 55 metres to 1,167 metres, and in four hauls in depths below 200 metres we were unable to detect any sign of living organisms on the bottom, which, as already mentioned, consists of a calcareous rock that appears to be in process of formation *in situ* In view of the enclosed character of the basin, the depth of the entrance channel at Great Hanish Island just to the north of the Straits of Bab el Mandeb being only some 160 metres, the water of the Red Sea below this depth, as is well known, has a very high salinity (40 per mille and above) and a high temperature (22°–23° C), though the oxygen content of the bottom water is higher than we expected to find and ranges from 1 32 to 1 65 c c per litre at depths between 800 metres and 1,500 metres in the northern part, sinking to less than 1 0 on the bottom in the southern area, but such conditions are of themselves scarcely sufficient to account for the complete absence of life.

The discovery of the second area, in which all life is either completely absent or is extraordinarily scanty, came as a complete surprise I have already referred to the region of the Arabian coast near Ras al Hadd, where we discovered a bottom deposit of soft green mud that smelt strongly of sulphuretted hydrogen, such an area we would expect to find largely, if not entirely, devoid of animal life, but this azoic area appears to extend far beyond the limits of the region where sulphuretted hydrogen is to be found and can be traced throughout the whole extent of the Gulf of Oman In this latter area the bottom consists of either a soft green mud or a grey clay, and between the depths of approximately 300 metres and 1,750 metres there is an almost complete absence of animal life, and even at so great a depth as 3,351 metres an hour's trawl only resulted in the capture of two starfish

In the accompanying tables I have given the various stations and their depths in the Gulf of Oman and off the Arabian coast, and it seems clear that this azoic area not only lies at a deeper general level in the Gulf of Oman than on the Arabian coast but also that there is a difference of level on the two sides of the Gulf of Oman The upper limit of the azoic area on the Arabian coast near Ras al Hadd lies somewhere between 83 metres and 102 metres and the lower limit between 1,253 metres and 1,536 metres The depth of the lower limit, however, probably increases as we pass towards the north-east, where we found prolific life at a depth of 952 metres, the trawl bringing up a number of fish and crustacea and thousands of Ophiuroids, in 1906 the R I M S *Investigator*, when trawling in the near vicinity, also secured a good catch, though the net was badly torn (*vide* Lloyd, 1907, p 2[1]) There can thus be little doubt that this area is a fertile one, but a little to the east at a depth of 1,253 metres we were within the zone of sulphuretted hydrogen and the catch after an hour's haul consisted of a single crab, *Paralomis* sp.

In the Gulf of Oman, the upper limit of the dead area appears to lie at a slightly different level on the two sides. On the southern side in the vicinity of Muscat the great bulk of the fauna disappears between 210 and 269 metres, though a few live animals were obtained at a depth of 610 metres, off the coast of Persian Makran no life was detected at a depth of 448 metres and it is somewhat significant that these levels correspond very fairly closely with the upper level of the deep inflowing mass of water that is running up the Gulf under the out-flowing Persian Gulf water That this water is not *per se* responsible for the absence of life is clearly shown by the results of several horizontal hauls at depths down to as much as 1,500–2,000 metres, for at all depths numerous red deep-sea prawns and small fish, such as *Bregmaceros* sp and Scopelids, were obtained It would appear, therefore, that the sterility of the area must be attributed either to some harmful character of the bottom deposit or else to some seasonal change in the general conditions of the deep water

ARABIAN COAST

Station No	Depth in metres	Character of bottom	Results
53	13	Rock *Lithothamnioneæ*	A good and varied catch
80	16–22	Sand and Shells	A good catch
45	40	*Lithothamnioneæ*, etc	A good and very interesting catch
43	83	? No sample obtained	A small but interesting catch
79	102	Green Mud (H_2S)	Very little animal life
48	201	Rock	A very small catch Net torn
77	350	Green Mud (H_2S)	A single crab, *Paralia alcocki*
56	457	Green Mud (H_2S)	No living organisms, dead shells of *Rostellaria delicatula* and *Encephaloides armstrongi*
57	428–750	Green Mud (H_2S)	Very little life, one dead shell of *Rostellaria delicatula* and a few moribund *Encephaloides armstrongi*
55	802	Stratified green mud	No sign of living organisms
54	952	Green mud and soft rock	A good catch, thousands of Ophiuroids
58	1253	Green mud (H_2S)	A single crab *Paralomis* sp
50	1536–1737	Brown mud	Catch very small
59	1977	Soft Green mud	Catch very small

The surface waters and the inshore areas in both regions, in marked contradistinction, appear to be particularly fertile Along the Arabian coast we have carried out several successful trawls, special attention being paid to areas where the charts indicate the presence of coral, in every case we have found that true reef-forming corals are absent, though we have dredged a number of specimens of *Lophohelia*, *Caryophyllia* and *Flabellum*, some still living though many of them dead The chief ingredient of the reef appears to be *Lithothamnioneæ*

GULF OF OMAN

Station No	Depth in metres	Character of bottom	Results
72	75	Grey clay and shells	A good and varied catch.
71	106	Grey-green mud and sand	A moderate catch
70	109	Soft green mud	Moderately good catch, 213 living examples of *Rostellaria delicatula* and several *Pirula* sp
75	201	Soft green mud	A good catch
67	269	Soft green mud	No living organisms, dead shells of *Rostellaria delicatula* and a few Serpulid tubes
64	448	Grey clay	No signs of living organisms
66	610	Brownish-green mud	Several dead shells of *Rostellaria delicatula* and 3 living examples, a few Serpulids
65	912	Green mud	No living organisms
68	1491–1518	Soft green mud	No living organisms
81	3350	Grey mud	Two starfish

Recent Discoveries at Choukoutien*

By PROF. DAVIDSON BLACK, F R S, Honorary Director, Cenozoic Research Laboratory, Geological Survey of China

UPPER PALÆOLITHIC CULTURE IN "UPPER CAVE" SEDIMENTS

A DETAILED account of the results of the Choukoutien excavations up to May 1933 has already been presented in our memoir "Fossil Man in China" (Mem Geol. Surv. China, Series A, No 11) In that report it was noted that above the *Sinanthropus* deposits there occurred towards the top of the hill a pocket of grey sediments of apparently modern facies, the site being described as the "Upper Cave". During the past season, Mr. W. C. Pei has systematically investigated the deposits of the latter site, ably assisted by Mr. M N. Pien. Their efforts have been rewarded by the discovery of much additional material of unexpected archæological significance

(1) *Sedimentary and lithological characters of Upper Cave deposits.* The "Upper Cave" was a true cave but became completely filled with a mixture of grey cave loam and angular flat limestone fragments, the latter being derived from the collapsed portion of its roof The roof is preserved over a quite large recess of the cave

---

* Report of excavations during the field season 1933, presented at the annual meeting of the Geological Society of China on November 11.

which extends to a smaller lower chamber not yet completely excavated. Where exposed, the cave walls are covered with stalactites and stalagmites. The grey Upper Cave sediments are largely unconsolidated and are in contact only over a few square metres with the hard red beds and stalagmitic floors capping the *Sinanthropus* strata of Locality 1. Elsewhere the Upper Cave appears to be developed as an independent system.

(2) *Fauna of the Upper Cave.* Though not very abundant, the Upper Cave fauna is remarkably rich in types and includes a puzzlingly large number of almost complete skeletons, the bones of which lie in correct association and are but slightly fossilised. The most interesting forms are as follows:—*Hyæna* (an extinct species very different from that found in the *Sinanthropus* beds but similar to that of Sjara-osso-Gol), *Felis tigris* (entire skeleton); *Cynailurus*, which is now restricted to India (an entire skeleton), *Viverra* (no longer found in North China), the wild ass, *Equus hemionus*, and the deer, *Cervus elaphus* (an entire skeleton), having antlers curiously similar to the special form from Sjara-osso-Gol.

(3) *Human and cultural remains.* In association with this fauna there occur both human skeletal remains and traces of industry. The skeletal remains are of modern type (*Homo sapiens*) and so far comprise two almost complete but somewhat crushed skulls, other skull fragments and teeth, fragmentary lower jaws, bones of the upper extremity (including one clavicle displaying a healed fracture), vertebræ, leg and foot bones. Traces of fire (charcoal and ash) are abundant.

There are three stone implements in a beautiful black chert, a well-made scratcher in vein quartz and several flakes and nuclei in vein quartz, and also a needle (eye broken), a deer canon bone worked at both ends, some thirty or more fox canine teeth perforated for necklace, an ornamental cylindrical piece made from a long bone of a bird, and a considerable quantity of oolitic hæmatite probably imported from a considerable distance. So far, no trace of pottery, polished stone or microlithic industry has been encountered.

Conclusions. The material recovered will shortly be made the subject of a full report and the conclusions here offered are wholly tentative. (*a*) The Upper Cave deposits appear to be decidedly younger than the *Sinanthropus* layers of Locality 1, from which they are separated by stratigraphic and lithological disconformity and by a faunistic interval (absence of thick-jawed deer, occurrence of a special *Hyæna*, presence of *C. elaphus*, *E. hemionus*, etc.). (*b*) The Upper Cave deposit is, however, probably also Pleistocene in age (collapsed cave, loess-like sediments, presence of Hyæna, cf. *spelæa*, *Cynailurus*, *Viverra*, *E. hemionus*, special deer, etc.). (*c*) In these circumstances, we are inclined provisionally to attribute the associated human remains to a Late Pleistocene, Palæolithic culture. The latter would seem to correspond approximately to the same stage as the Upper Palæolithic of Siberia and Europe. It appears, however, to be somewhat more advanced than the Ordos industries (Shui-tung-ko and Sjara-osso-Gol) in which no typically worked bones have thus far been found in certain association.

Cynocephalus REMAINS

In a cylindrical solution cavity about a metre in diameter in the limestone to the south of Locality 1, Mr. M. N. Pien discovered this season a considerable number of fossil bones imbedded in a peculiar red deposit containing a large proportion of small well-rounded pebbles. These bones are remarkably fossilised and heavy, many of them being water-worn and rounded. A few, however, are well preserved, among the latter being several teeth and limb bones of a large baboon, probably *Cynocephalus wimani*, Schlosser. Strikingly similar deposits containing the same type of heavy rolled bone fossils have already been encountered at the very base of the *Sinanthropus* deposits of Locality 1 (Lower Cave). At the present stage of excavation it remains an open question whether or not these beds represent a pre-Choukoutien stage or merely correspond to an early phase in the last filling of the clefts.

In any case it would seem that one must conclude from this latest discovery that the Choukoutien fissures have been successively inhabited by baboons, by *Sinanthropus* and by a modern type of *Homo*. However, such a coincidence appears less extraordinary when it is recalled that though Ordovician limestone is widely distributed along the Western Hills, at Choukoutien, on account of its low anticlinal structure at the borders of the plain, it is exceptionally well situated for dissection into fissures and caves.

Obituary

PROF. J. JOLY, F.R.S.

JOHN JOLY came of a remarkable lineage. His father's grandfather was a member of a French noble family. His mother, a German countess, whose family had been ennobled by Frederick the Great, was descended from Greek, Italian, and English ancestors. This mixture of blood, perhaps, may explain his ready sympathy with the most diverse personalities, his princely generosity which often gave to others what he denied to himself, and his versatility which enabled him to prosecute research in so many fields of knowledge, and to obtain æsthetic pleasure in the realms of art, literature, music and science.

Joly's earliest papers were mostly occupied with mineralogy. The beauty of the colour and form of minerals had a marvellous attraction for him. In this period he wrote on the ash of Krakatoa, beryl, iolite and harmotome. Investigation on these minerals led him to devise the meldometer and apophorometer, by means of which he determined the melting points of minerals with the greatest accuracy, and was able by volatilisation to reveal their constituents in a much more elegant and delicate way than by the blowpipe. About this time also he devoted some attention to the problem of accurate photometry and devised the well-known diffusion photometer. Next followed the invention of the steam-calorimeter, which not only enabled him to determine with greater accuracy than ever before the specific heats of minerals, but also put into the grasp of his imaginative mind the power of determining directly the specific heats of gases at constant volume In this way he solved an experimental problem which had the highest importance in molecular theory. In 1892, doubtless in recognition of this achievement, he was elected to the Royal Society

By a beautiful novel method Joly obtained the volume change of rocks and minerals on fusion, and so contributed accurate and important data to geophysics His experiments with electrically heated furnaces enabled him at a very early period to isolate aluminium from aluminium silicates, but unfortunately a discouraging word from a senior deterred him from publishing the result, and so others obtained the credit for this method of reducing the element During this period, photographic work became absorbingly interesting to him, and he investigated the relation of the sensitivity of the photographic film to temperature, and suggested the electronic theory of the latent image He invented shutters for use in stellar photography and a photographic method for the detection of variable stars But in this field his most arresting invention was the method of colour photography by which he rendered it possible for the first time to reproduce with accuracy on a single transparent plate the colours of Nature At about the same time, his attention was directed to Lowell's observations on the canals of Mars Contrary to the received statements that these markings on the surface of the planet were all portions of great circles, Joly perceived that this was not the case, and he showed that all could be traced by moons rotating near the surface of the primary, and so propounded a rational physical theory. Another essay of astronomical bearing, startling alike in its imagination and literary style, is his "Theory of the Prematerial Condition of the Universe."

Biological speculations frequently kindled Joly's imagination, and in essays on the bright colours of Alpine plants, and on the abundance of life, he made contributions to biological philosophy which are too often neglected In collaboration with one of the writers of this notice, he formulated the cohesion theory of the ascent of sap, and devised and carried out several novel and beautiful experiments with plants. Here also should be mentioned his speculations on the connexion between cosmic rays and cellular evolution, morbid and normal.

Time and again Joly returned to his first love of mineralogy and geology, and his work on the thermal expansion of the diamond, the action of the ions of sea-water in sedimentation, and the influence of pressure on the order of formation of minerals in igneous rocks, ingeniously made use of physical principles for the solution of long-standing problems. Experiments on solvent denudation led him to formulate his method of determining the geological age of the earth by the sodium content of the ocean The period yielded by this method in its early stages is now generally considered to be an under-estimate, but it must be remembered that, at the time, it materially and rationally extended the much more crippling estimate of the earlier physicists In this connexion may be mentioned the attractive spell the sea exercised on his mind, and while he sailed in small boats or in large ships, geological problems were not the only ones which occupied his thoughts In these surroundings he devised a method of observing the altitude of a celestial object at sea during nighttime, or when the horizon is obscured , he devised the collision predictor and synchronous signalling, an explosive sounder, two types of borers for obtaining samples of sediments and rock from the sea bottom, and floating breakwaters whereby the energy of the breaking waves is transformed into turbulent movements round the keel of a floating vessel

It is, however, in the field of the application of the heat-producing properties of the radioactive elements to geophysical problems that Joly did some of his best-known work So early as 1903, when Pierre Curie and Laborde first definitely established the continuous heat-production of radium, he pointed out the importance of this fact in geological science and its bearing on Lord Kelvin's view of the age of the earth, which was based on thermal considerations The first actual detection of the wide distribution of the radioactive elements in terrestrial surface materials was due to the present Lord Rayleigh in 1906, but afterwards Joly and his pupils devoted much attention to this problem, and measurements on materials from most parts of the globe have been made in his laboratory. In 1909 he devised his method for the measurement of thorium in a rock, a problem previously unattacked, and in 1911 his well-known furnace method of determining the radium content of a rock.

Joly's early views on the effect of radioactivity on earth history are contained in his book, "Radioactivity and Geology" (London. Constable and Co., 1909). His theory of the production of pleochroic halos by α-ray disintegration also dates from about this period. In conjunction with Lord Rutherford he devised a new method of deducing the age of the mineral containing the halo, which gave results for geological ages more in accordance with the other radioactive methods than his previous method based on solvent denudation. In subsequent years he expended much time in further investigation of these halos, obtaining many interesting results, among which may be mentioned his discovery of an unknown radioactive element, which he provisionally named hibernium. During the past year, this element has been shown by G. Hevesy and M. Pahl to be samarium.

Joly's general interest in all radioactive problems, and his great sympathy with human suffering, led to the foundation of the Irish Radium Institute by the Royal Dublin Society in 1914. He was both the originator and strong advocate of this Institute, and its present highly satisfactory condition is largely due to him. Among those to whom Joly was personally known, it would, we think, be unanimously agreed that, of all his many activities, this was the one nearest his heart, and for which he would best like to be remembered. The so-called Dublin method of using radon in fine capillary glass tubes, which can be placed inside hollow metal needles, was first developed by him, and his life-long friend, the late Dr. Walter Stevenson. This method of using radon and not the actual radium salt has always been employed at the Irish Institute, and has also been adopted at many other centres. To the end, his interest in radium therapy never failed; some of his most recent papers, read before the Royal Dublin Society, deal with improvements in its technique. These include the use of native radioactive powders and a mechanical means of focusing γ-rays on deep-seated tumours.

During the War, Joly devoted his attention to various technical problems. At its conclusion, he returned to the study of radioactivity, and was among the first to attempt the separation of the lead isotopes by physical methods. Later he became interested in the problem of vision, and developed a theory of colour vision based on the quantum theory of photoelectric emission and the physiological structure of the retina. In 1923 he was asked to determine the radioactive contents of some South African rocks, and this led him to a reconsideration of the effect of radioactivity in geological history. From this sprang his theory of thermal cycles, which he has so brilliantly presented in his book on the surface history of the earth. The publication of this work is a landmark in the advance of geological science, focusing, as it does, the attention of geologists on the enormous importance of radioactivity in earth history, and giving a rational explanation of the succession of revolutions and geological strata. His subsequent work, mostly carried out in conjunction with one of the present writers, was largely devoted to further radioactive measurements, in the course of which the very low radium content of the eclogites was established, a fact of great interest in geological theory.

John Joly was born in Hollywood, King's County, in 1857. His early education was obtained in Rathmines School. In his school-days, which for various reasons were short, apparently he attracted no special attention in the usual educational tests, but won great popularity among his fellows by his powers of narration and the original tales which he contributed to the school magazine. While at Hyères, where he went for his health, he constituted himself 'foreign correspondent' and published many notes on the natural history of the south of France. Owing to these activities, he acquired among his school-fellows the title of 'the Professor', a title by which he was always known among his oldest friends.

In college Joly was omnivorous in his reading, but always refused to be limited by examination courses, and so it happened that while he studied physics, chemistry, mineralogy and modern literature with zeal, his only academic distinction was first honours in English literature. In the engineering school, however, his soundness and originality were recognised and he was placed at the top of the list in all subjects at the B.A.I. examinations. After his degree he held minor posts in the engineering school and in the school of physics, and while still FitzGerald's assistant, he had already attracted attention by his early inventions and researches in mineralogy and calorimetry. In 1897 he became professor of geology at Trinity College, Dublin, and though he received many offers of more lucrative posts, he remained until his death on December 7 last a Trinity man. Throughout his career, he kept in close contact with the students, and formed and accomplished many schemes for increasing undergraduate amenities. He was keenly interested in the scientific development of T.C.D., and was the originator and secretary of the science fund whereby T.C.D. acquired the present schools of physics and botany, with their equipment and most of their endowment. The special research endowment of the school of geology by the late Earl of Iveagh was a recognition of his personality and distinction as an investigator. He acted for many years as secretary to the Academic Council and was a member of the Board of T.C.D. In 1919 he was elected to a fellowship in the College.

Outside his College also Joly had many activities. He was successively member of council, secretary, vice-president and president of the Royal Dublin Society. He contributed many papers to its *Transactions* and *Proceedings*, and interested himself in every way in its welfare, and in forwarding its aims. He was warden of the Alexandra College and was one of the delegates of the Balfour Educational Mission to America in 1918. On the Board of Irish Lights he was one of the most active commissioners, and delighted to put his scientific knowledge and inventive mind at its service. He was also a governor of two Dublin hospitals. In his earlier days he was a keen Alpine climber, and yachtsman, and many of his researches were planned and his philosophical and speculative writings discussed with his companions on these expeditions. His fundamental method of treatment, his extraordinary originality and intellectual fertility, and his æsthetic appreciation of Nature made these conversations unforgettable by those who had the good fortune to be with him.

HENRY H. DIXON.
J. H. J. POOLE.

Mr. H. F. Biggs

We regret to record the death at Oxford on January 9 after a short illness of Mr. Henry Francis Biggs, whose place in the University as a tutor in physics will be difficult to fill. In spite of severe calls on his time and energy in the fulfilment of his academic work, he took a keen interest in the latest developments of physics, and contributed to the columns of this journal and to other scientific journals. His main published works are an "Introductory Sketch on Wave Mechanics" and a monograph on "The Electromagnetic Field", the latter of which appeared only a few days before his death.

Mr. Biggs went to Oxford in 1919 as a demonstrator in the Electrical Laboratory under Prof. J. S. E. Townsend, and took an active part in the teaching of physics in the University. He had a varied experience of academic life, having studied at Trinity College, Dublin, and at Cambridge, and having held a lectureship at the South African College (now the University of Cape Town), and later a lectureship at the University of Manchester. During the War he was attached to a sound ranging unit, where his theoretical knowledge, his practical skill and inventive ability found abundant scope.

Mr. Biggs will be greatly missed by his pupils and colleagues, who will long cherish the memory of a cultured, courteous and interesting personality.

We regret to announce the following deaths:

Sir William Lawrence, treasurer of the Royal Horticultural Society, 1924-29, formerly lecturer in organic chemistry in the University of Manchester, on January 4, aged sixty-three years.

Sir Donald MacAlister, K.C.B., Chancellor of the University of Glasgow since 1929, and president of the General Medical Council in 1904-31, on January 15, aged seventy-nine years.

News and Views

Dr. Harlow Shapley

The Gold Medal of the Royal Astronomical Society has been awarded to Dr. Harlow Shapley for his studies of the structure and dimensions of the galactic system. Dr. Shapley, who was born on November 2, 1885, has been director of Harvard College Observatory and Paine professor of astronomy at Harvard since 1921, succeeding E. C. Pickering. He is known particularly for his development of the period-luminosity law of the relation between the period of variation and the absolute magnitude of Cepheid variable stars. The apparent magnitude of the Cepheid variables in a globular cluster is measured and compared with the known absolute magnitude of a Cepheid of the same period, and from this the distance of the cluster is obtained immediately, provided absorption of light in interstellar space is negligible. In 1915-18 he published a noteworthy series of papers on researches on the globular clusters which brought these objects prominently before astronomers. His principal results were brought together in 1930 in his "Star Clusters". Dr. Shapley's investigations have been applied at Mount Wilson by Dr. E. P. Hubble to measure the distances of the spiral nebulæ. Recent papers from the Harvard College Observatory have discussed the distribution of the galaxies and the uniformity of distribution of matter in space. Dr. Shapley is a member of the United States National Academy of Sciences and an associate of the Royal Astronomical Society.

Colwyn Gold Medal of the Institution of the Rubber Industry

The Colwyn Gold Medal of the Institution of the Rubber Industry has been awarded to Dr. O. de Vries, until 1930, director of the Rubber Station, Buitenzorg, for scientific work in connexion with the production of raw rubber. The medal was presented to Dr. de Vries by Sir George Beharrell, president of the Institution, on the occasion of the twelfth annual general meeting of the Institution held on January 12. Dr. O. de Vries has devoted the best part of two decades to the investigation of plantation rubber problems. His work at the Buitenzorg Testing Station in Java brought world wide fame not only to the Testing Station but also to himself. It covered a large number of problems of various types which arise between the growing of the tree and the eventual vulcanisation of the rubber in the distant factories. He cleared up many obscure plantation practices, indicating the reason, if any, for their existence. Dr. de Vries overhauled and set new standards in methods for testing plantation rubber. His investigations contributed to the further standardisation of plantation rubber and its characteristics in respect to vulcanisation and mechanical qualities. The principal aspect of Dr. de Vries's work has been his desire to ensure its availability throughout the world. The result of his investigations were published in Dutch, but with a generous disregard for the labour entailed, the publication of each investigation was accompanied by a version in English. Similarly in 1920 he produced an English translation of his well-known book on "Estate Rubber", the original Dutch version of which appeared in the following year. This book is a lasting monument to his activities.

Early Man in China

Further exploration at Choukoutien has resulted in discoveries which, if less sensational than that of Peking man, are none the less of considerable importance as additions to our knowledge of the distribution of palæolithic industries and of 'modern man' in late pleistocene times. According to Prof. Davidson Black's report on field-work at Choukoutien in 1933, which was presented at the annual meeting of the Geological Society of China on November 11, and appears in this issue of NATURE (p. 89), Dr. W. C.

Pei and Mr. M. N. Pien, in excavating the grey sedimentary deposits of what is known as the "Upper Cave", have discovered human skeletal remains in association with a fauna, in part extinct, implements of stone and bone and abundant traces of fire and charcoal. These sedimentary deposits were largely unconsolidated and in contact only over a few square metres with the hard red beds and stalagmite floor capping the strata in which the relics of *Sinanthropus* were discovered. The human skeletal remains include two skulls, which fortunately are complete, though said to be "somewhat crushed", so that there should be no question of the correctness of their attribution to *Homo sapiens*. Full description of their specific characters will be awaited with the greatest of interest, as the first specimens of 'modern man' of palæolithic age to be found in China. In view of the character and associations of the discovery, subsequent consideration should confirm rather than controvert Prof. Black's tentative conclusion as to the late pleistocene dating of the find and the correspondence of the industry with the Upper Palæolithic of Siberia and Europe. The further discovery of fossilised bones of baboon, upon which Prof. Black bases a sequence of baboon-*Sinanthropus-Homo sapiens*, points to conditions at Choukoutien which will repay exhaustive study of the site.

Indian Earthquake of January 15

AN earthquake of considerable strength and of much interest occurred in Northern India at about 2.40 p.m. on January 15. The loss of life was larger than at first appeared, 61 deaths being officially reported in the Patna district, 1,000 unofficially reported at Muzaffarhur, and smaller numbers in other districts. In its long duration and immense disturbed area, the earthquake possesses two features of a great destructive shock. An interesting point in the recent earthquake is its probable connexion with the great earthquake of June 12, 1897, described by Mr. R. D. Oldham in a report which is one of the most valuable that we possess on any earthquake. The places that suffered serious damage are (from east to west) Jamalpur, Darjeeling, Patna, Gaya (Bihar), Benares and Cawnpore. Jamalpur lies within the epicentral area of 1897. All the others are included within an area about 600 miles long from east to west. The epicentre thus seems to lie about 350 miles to the west of that of 1897. At Calcutta, about 300 miles south-east of the epicentre, the shock was so strong that the seismograph at Alipore was put out of action. The shock there is said to have lasted 8 min., the violent motion in the middle continuing for 1½ min. Durations of 5 min. at Cawnpore and 3 min. at Delhi are also reported, but strong after-shocks may be included in such estimates. At Jubbulpore (about 350 miles from the epicentre) houses were shaken so strongly that people hurried into the streets. Even at Bombay (more than 800 miles), a mild shock was felt.

THE area disturbed by the earthquake may thus amount to as much as two million square miles, or about the same as that over which the Assam earthquake of 1897 and the Kangra earthquake of 1905 were felt. The whole Himalayan arc is bounded by four great seismic regions, namely (from east to west), Assam, Nepal, the Punjab and Cashmere. Denoting these regions by the letters *A*, *B*, *C*, *D*, and confining ourselves (with one exception) to great destructive shocks, we have the following succession of areas disturbed: *D* 1828, *C* 1832, *B* 1833, *A* 1869, *B* 1869, *C* 1875 (semi-destructive), *D* 1885, *A* 1897, *C* 1905, *B* 1934, a continuous migration from *D* to *A* and back again to *D*, followed by an oscillation to the east in 1897, back to the north-west in 1905, and ending in the intermediate region in the present year.

Wave-length Changes of European Broadcasting Stations

ABOUT an hour before midnight last Sunday, January 14, a large proportion of the broadcasting stations in Europe adjusted their wave-lengths to conform with the provisions of a scheme evolved at a conference of the International Broadcasting Union held at Lucerne in May and June 1933. The object of this Lucerne Plan was to effect such a distribution of wave-lengths from a geographical point of view that the amount of interference caused to the service of any broadcasting station should be reduced to a minimum. To assist in the matter, the Plan also provides for certain maximum power limitations which differ according to the wave-length range. Unfortunately, the operation of the scheme at the present time is not completely successful because several countries declined to sign the agreement, while a few individual stations are also not abiding by the terms applicable to their country. During the first portion of the change-over programme, each broadcasting station adjusted its wave-length with the aid of its own national calibrating station. Then at about 2.30 a.m. on Monday morning the Brussels Checking Station of the International Broadcasting Union began to check the wave-lengths of the stations at the rate of twenty-four an hour, this procedure continuing until about 7.30 a.m. This checking process was resumed during Monday night after the cessation of the normal programmes.

ON the medium wave-lengths band, the changes were carried out without much difficulty and when the final adjustments have been made at certain stations, it is expected that European reception of broadcasting in general will have been appreciably improved. On the long-wave band, however, certain difficulties have resulted from the non-compliance of some countries and stations with the provisions of the scheme, but it is hoped that a convenient compromise will be reached in the near future. Listeners to British stations will not experience much difficulty in finding their new tuning adjustments, for except in the case of Bournemouth, the change was fairly small. A useful pamphlet, entitled "The Lucerne Plan", explaining the wave-length changes has been published by the B.B.C., and some of technical periodicals such as the *Wireless World* and *World Radio* have provided useful charts by means of which the new position of any European station on the wave-length scale can be ascertained.

New Chemistry Building at University of Leeds

SIR FREDERICK GOWLAND HOPKINS, president of the Royal Society, formally opened the new chemistry building at the University of Leeds, on January 12, in the presence of the Pro-Chancellor of the University, Col C. H. Tetley, the Vice-Chancellor, Sir James Baillie, and a representative gathering of past and present members of the University and of visitors from other universities. Sir Frederick Hopkins, in an address entitled "Modes of Thought in Chemistry", stressed the importance of chemical knowledge for national progress and emphasised the importance of experimental inquiry in pure chemistry, one of the fundamental sciences. In a critical and stimulating discussion of the differences in the habits of thought of workers in the several sections of pure chemistry, he dwelt on the great results which have been achieved especially in organic chemistry by the use of a mode of thought essentially pictorial and non-mathematical, which is as necessary as the more quantitative methods of the physical chemist. After the ceremony in the large lecture theatre, an inspection was made of the new laboratories The rapid growth of the Department under Prof Arthur Smithells, who succeeded Sir Edward Thorpe and by whose efforts the chairs of organic and physical chemistry were instituted, called for an extension of space but for many years the only quarters available were buildings of a temporary nature and geographically separated. Now, thanks to the generous response of the public and the policy of the University Council, all the various sections of pure chemistry have been gathered together under one roof in a new building facing Woodhouse Lane, which forms the latest addition to the general scheme for the extension of the University of Leeds

Ball Lightning

PROF. J C. JENSEN, of Nebraska Wesleyan University, Washington, describes in *Physics*, vol. 4, October, 1933, how he was fortunate enough to photograph ball lightning when he was taking photographs of ordinary lightning in an August thunderstorm. The display of lightning was taking place in the region of the outrushing cold squall in advance of the main mass of the storm, and this squall was carrying with it great quantities of dust. In the wake of one of the flashes came the globular lightning, apparently floating slowly downwards. Two or three brilliant globular structures of the kind known as ball lightning appeared to travel along a pair of high-voltage power lines for a considerable distance, eventually falling to the ground and disappearing with a loud report. Two are clearly visible on one of the photographs, and, as their distance was known, it was an easy matter to determine their diameters, which were found to be very much larger than numerous observations of the phenomenon made elsewhere would have led one to expect, namely, 28 ft. and 42 ft. Unfortunately, ball lightning is so rare compared with ordinary lightning that the much desired confirmatory evidence of the occurrence of such large globular structures that might result from further photographs may be a long time in coming There seems no doubt from the repeated observations of ball lightning made inside houses, and from the size of holes made by it through window-panes, that it is generally much smaller.

Mind, Brain and Survival

DR WILLIAM BROWN, lecturing on "Modern Science and the Possibility of Survival", at the Survival League at Caxton Hall on January 11, discussed the various theories of relation of mind to brain, and expressed the view that nothing firmly established in modern science makes personal survival after bodily death intellectually inconceivable But the task of obtaining reliable evidence is beset with enormous difficulties The results and messages in mediumistic trance should be closely scrutinised in the light of modern knowledge of the psychology of the unconscious, and sifted with due regard to the statistical laws of chance coincidence Spontaneous psychic experiences on the part of private individuals, though more reliable in other respects, are specially difficult to assess statistically There is little doubt that a large proportion of the apparent evidence for survival has to be rejected by strict science ; but when all the sifting has been done there remains a small residuum very difficult to explain Phenomena can only be fitted into a scientific system if their conditions of causation are known, and this is far from being the case with psychic phenomena, although some of the more general conditions are being gradually revealed. Very thoroughgoing psychological analysis of selected mediums will advance our knowledge considerably in this dim borderland of science, and may indicate further lines of investigation.

Administration and Management in Industry

THE number of societies and institutions dealing with the administrative or managerial side of industry is now very considerable and covers a wide and varied field in works management, costing, salesmanship, advertising, research, etc. That there is plenty of work and scope for organisations of this sort is evident enough, but there is certainly some ground for supposing that their number may soon become excessive, and some at least may be unable to obtain sufficient financial support to keep going, especially since the subscription rates are necessarily rather high and correspondingly onerous to manufacturers and their executives in these difficult times. From its name, the Institute of Industrial Administration should be capable of covering the whole territory, but it has many rivals It is to be hoped there is room for all, and that there will be no desperate struggle for survival The Institute held its annual general meeting on December 12, and an increase in the subscription of corporate members from 3 guineas to 5 guineas was recommended. This is to be interpreted, we hope, as a measure of increased usefulness to members rather than as an expiring clutch for more funds. The papers presented at the 1932–33 session have just been published, on

'Roneod' sheets bound in paper covers (London: Institute of Industrial Administration, 1933. 5s.). They are none the worse for this, and two of them deal in an effective manner with difficult problems of distribution, and another is on research in industry, by Mr. A. P. M. Fleming.

In few branches of social study, however, is there a greater tendency to discursiveness and mere talk than in these various divisions of industrial administration, especially in salesmanship and advertising; and in fewer still is there a greater misuse of the term 'science'. In the papers here published it must be admitted that this tendency is little in evidence. They are indeed bright, brief and stimulating. The discursive tendency is perhaps exhibited most in the first paper on personal and impersonal management, by H. N. Munro, although his theme, so far as it can be definitely apprehended, seems sound enough. The next two papers, on distribution, are well worth reading and serious reflection, not only because this subject is one of the most important and difficult in the present age, but also because the authors strongly condemn that 'production complex' which is still too much in evidence in industrial management. One of them, based largely on personal experience, has an air of convincing reality and logic which is very attractive. It is scarcely necessary to say that Mr. Fleming's paper on research is characterised by his usual methodical and orderly presentation, and overwhelming arguments in support of far-sighted research policies and carefully thought-out research programmes. Other papers deal with finance and secretarial duties.

Flood and Erosion Control

Among the various expedients put forward for dealing with the problem of unemployment in the United States, one of considerable interest from a scientific point of view is that of Dr. L. E. Freudenthal, chairman of the Institute of Irrigation Agriculture, American Farm Bureau Federation, Las Cruces, N.M. In an address to the South-Western Division of the American Association for the Advancement of Science, which appears in *Science* of November 17, 1933, he points out that flood and erosion control are matters of national importance in America in that they are beyond the capacities of individual States to deal with. He instances the huge sums of money which have been beneficially expended on water supply, irrigation, water power and waterway undertakings and the equally enormous losses of life and property due to floods and erosion. The Mississippi flood of 1927, which inundated 18,000 square miles, drove 750,000 persons from their homes, did some 300,000,000 dollars worth of damage and took 246 lives, is, he states, an example of what is happening annually on a smaller scale in nearly every State. For the last twenty years, flood damage in South Carolina and Tennessee has averaged nearly one million dollars per annum.

The attendant erosion of fertile lands is stated by Dr. Freudenthal to be a national menace and he quotes a report of the U.S. Bureau of Soils to the effect that not less than 126 billion pounds of plant food material is removed from the fields and pastures of the United States every year, the value of the plant food elements in the waste being 2½ billion dollars annually. Erosion, adds Dr. Freudenthal, has been the principal cause for abandoning millions of acres of cleared land, and he goes on to suggest various directions in which Government assistance might be rendered in the matter of flood control measures with the object of providing relief for unemployment, including stream regulation, tree and brush planting, contour furrowing, protective fencing and seeding. He believes that flood and erosion control work are ideally suited for unemployment relief, not only for the reasonably effective results which could be obtained, but also because of the possible excellent effect upon the unemployed themselves.

Darwin's Parish

Sir Buckston Browne's generous gift to the British Association, in trust as a national possession, of Down House, Charles Darwin's home for forty years, and his further benefaction of the Research Farm of the Royal College of Surgeons at Downe, have revived the association with science of a secluded Kentish village which has retained much of its rural character, although within twelve miles of Charing Cross. It is sometimes forgotten that Downe was the residence of the Lubbocks and that it was here that John Lubbock, afterwards the first Lord Avebury, entered into the close and lifelong friendship with Darwin which exercised so great an influence on his scientific work. It is only reasonable to expect that those who visit Down House, now that it has become a place of scientific pilgrimage, should wish to know more of the history of its village. This need has been met in a little book ("A History of Darwin's Parish: Downe, Kent", Russell and Co., Southern Counties Ltd., Southampton, pp. viii + 88. 1s. 6d.) written by Dr. O. J. R. Howarth, secretary of the British Association, and Mrs. Howarth, with a foreword by Sir Arthur Keith, now also a resident of Downe. The parish history has nothing sensational to relate; but apart from the association with Darwin, it is interesting as a record of the life of a typical secluded English village—a life, which as the authors allow us to see by their skilful selection from humdrum records, was not without its humours and its tragedies. The evidence, which, so far as written documents are concerned, begins about A.D. 1100, is fragmentary at the best; but the authors have made the most of their material and have produced a really informative and interesting account of the parish.

Psychology in Germany

The German Psychological Association's proceedings at its thirteenth congress, held at Leipzig on October 15–19, are reviewed in a thoughtful article, "Psychology under Hitler" by Goodwin Watson of Columbia University, in *School and Society* of

December 2. In that assembly of more than six hundred, Jewish members of the Association, among whom are many who have been leaders of psychological thought, were conspicuous by their absence—and an opening address emphasised the demand for a psychology which expresses the genuine German spirit. *Gestalt* concepts were much in evidence and underlying all discussion was the assumption that parts are influenced by their membership character in larger wholes. It seems clear that "German psychology is developing a special concern for the type of *Gestalt* which is not limited to the perceptual field, but gives us the essential way of life of a whole personality". Of great practical significance was the address of Poppelreuter on political psychology. This directs attention to an increasing preoccupation with character and life as against intellect and theories and to the change of attitude brought about by the Hitler revolution, a change from an attitude of helplessness to one of determination to create, from disunity in economic ideas, political programmes, morality and world views to a sense of a common purpose. In the new whole of German culture, psychology no less than the other sciences must contribute to the realisation of the common purpose. "American psychologists," says Dr. Watson, "surveying the scene as spectators, may well wonder how long they can retain their own very considerable isolation from the major tasks of our generation." Coming as it does from the most influential focus of psychological doctrine in the United States, the comment is not without a certain piquancy.

History of the Parsons Steam Turbine

THE first issues for 1934 of the *Engineer* contain two instalments of a series of articles to be devoted to the development of the Parsons steam turbine. It is just fifty years since Sir Charles Parsons took out his patents for improvements in electric generators and improvements in rotary motors actuated by elastic fluid pressure, and constructed his first turbo-generator. This machine developed about 7·5 kw. To-day single turbo-generators of 100,000 kw. capacity are in use, and the present estimated value of Parsons turbines alone is £152,000,000, the figures for marine and land turbines being £92,000,000 and £60,000,000 respectively. Nothing to equal that rapid extension of value and dimensions has ever happened before. The publication of the series of articles will take many weeks and will appropriately mark the jubilee of this great invention. The first article contains a detailed description of the original turbo-generator, while the second, after referring to the early development of the parallel-flow turbines, deals with the radial-flow turbines of 1889–91.

Automatic Voltage Control of Electrical Systems

THE problems which arise in connexion with maintaining the voltage of supply constant in electrical distributing systems have been closely studied by electrical engineers during recent years. The permissible variation allowed by the regulations is plus or minus four per cent of the 'declared' voltage, but the average regulation is much closer; the houses near the supply station at times of maximum load are supplied at a voltage above the declared pressure and the few near the ends of the distributing mains at a voltage below the normal. The lamps near the supply station therefore give a better light and have a shorter life than the distant lamps. In a paper read by W. Kidd and J. L. Carr to the Institution of Electrical Engineers on December 7, methods of automatic voltage regulation and switch control were described. The city of Manchester is the first area to have complete automatic voltage regulation and it also has supervisory control for its main sub-stations. By a careful application of automatically controlled regulators it is shown that the voltage on distribution networks can easily be maintained within the permissible limits. Manual control of voltage is never quite satisfactory and necessitates the uneconomic employment of additional labour. The installation of the regulating equipment gives better service to the public and removes a possible cause of complaint. It has to be remembered that a rise or fall in the voltage of one per cent increases or diminishes the light emitted by the lamp by about three per cent. Several diagrams are given showing methods of adapting existing transformers by means of automatically controlled tap-changing devices so that the voltage of supply can be kept constant at all loads.

Organisation of a Social Centre

IN a recently issued publication entitled "The Centre" (London: P. S. King and Son, Ltd. 3*d*.) various problems confronting the organisers of social centres for the unemployed are discussed by five contributors, who have had experience in the running of such centres. Special emphasis is laid on the importance of not losing sight of the individual in the mass, and of adapting the facilities provided to the needs of the individual. To prevent employables from becoming unemployable, though most desirable, is but a small part of a centre's activity. The way social centres can help best is to aid the individual to discover new powers, since this is the key to re-creation and progress. One person may need opportunities for thinking (study, reading, talks or discussions); another may wish to make something; another may prefer some form of amusement (a game, dancing, gymnastics); others again may want advice as to cooking food, mending boots, making clothes or keeping well. It is no part of the purpose of a centre to compete with or undercut existing employment. It is conceivable that certain articles such as handwoven scarves might find a ready market, but the repeated manufacture of products of the same kind is not the aim of a social centre. The work there should be undertaken for the sake of the effect which the making has upon the maker. Its purpose is to perfect the individuals and this will not be obtained by encouraging them to do the same thing over and over again.

Non-Reflecting Windows

In connexion with the note under this title in Nature of January 13, p 59, a correspondent points out that the principle can be applied to the glazing of pictures and of museum cases, both of which applications were explained and discussed, with illustrations, in the *Museums Journal* of November 1932 (pp 305–308).

The Zoological Station, Naples

The attention of British zoologists, botanists and physiologists is directed to the facilities for research available in the Zoological Station, Naples A Committee of Section D (Zoology) of the British Association is empowered to nominate competent research workers to a table in the Naples Station which has been maintained by the British Association since 1876 Workers so nominated are provided, without charge, with material and ordinary chemicals and apparatus The Station possesses a considerable range of apparatus for physiological and biochemical investigations Applications for the use of the table should be sent to the Chairman and Secretary of the Committee, Prof J H Ashworth, Department of Zoology, The University, Edinburgh, and should specify the nature of the research proposed and the period for which the table is desired

Geological Society Awards

The following awards of the Geological Society of London have been made for this year The Wollaston medal to Sir Henry Miers, honorary professor of crystallography in the University of Manchester, for his researches on the mineral structure of the earth, and especially in the realms of crystallography and mineralogy, the Murchison medal to Prof George Hickling, professor of geology in Armstrong College, Newcastle on-Tyne, for his contributions to geological science in many branches, but especially in the stratigraphy of the Coal Measures and the structure of coal, a Lyell medal to Dr Finlay Lorimer Kitchin, of H M Geological Survey, in recognition of the value of his contributions to palæontological science, another Lyell medal to Prof Walter Howchin, emeritus professor of geology and palæontology in the University of Adelaide, South Australia, for his geological and palæontological researches in Australia and particularly for his investigations of ancient glacial deposits, Wollaston fund to Dr. William Richard Jones, of the Royal School of Mines, in recognition of the value of his work in economic geology and his recent investigations in silicosis, Murchison fund to Dr Wilfrid Jackson, assistant keeper in the Manchester Museum, for his contributions to Pleistocene geology and palæontology and to malacology, Lyell fund to Mr. Frederick William Shotton, in recognition of the value of his work on the Upper Palæozoic and Quaternary rocks of the Midlands

Announcements

Dr W Cawood has been appointed to a Moseley research studentship of the Royal Society, for work on the accurate determination of molecular weights of gases.

Upon the retirement from the public service of Dame Janet Campbell, as from December 31 and of Sir George Buchanan, as from February 18, Dr. Jane H. Turnbull will be in charge of the Maternity and Child Welfare Division of the Medical Staff of the Ministry of Health and Dr J M. Hamill will act as senior medical officer in charge of the Foods Division of the Ministry.

At the annual general meeting of the British Ecological Society held at Cambridge on January 2–4, the following officers were elected. *President*, Prof. J R Matthews; *Vice-President*, C. Oldham; Hon. Editor of the *Journal of Ecology*, Prof. A. G. Tansley; Hon. Editor of the *Journal of Animal Ecology*, C S. Elton; Hon. Secretary, Dr H. Godwin. The Council unanimously approved the nomination of Prof H. C. Cowles and Prof. L. Cockayne for honorary life membership of the Society

The twentieth International Congress on Alcoholism will be held at the Imperial Institute, South Kensington on July 30–August 3 under the presidency of Lord Astor The aim of the Congress is to secure a comprehensive world picture of the present position concerning alcoholism in its various ramifications in social life. The mornings will be devoted to the consideration of national surveys, and the afternoons to papers on education, the influence of legislation on the consumption of alcoholic beverages, alcohol in the treatment of disease, the causes and treatment of inebriety, alcohol and eugenics, alcohol and heredity and the organisation of press work All communications concerning the Congress should be made to the convener, Dr C C. Weeks, 33 Bedford Place, W C 2.

Applications are invited for the following appointments, on or before the dates mentioned —Examiners for the Aeronautical Inspection Directorate of the Air Ministry—The Secretary (S.2), Air Ministry, Adastral House, Kingsway, London, W C 2 (Jan. 26). A lecturer in pharmaceutical chemistry in the Department of Pharmacy in the Birmingham Central College—The Principal, Central Technical College, Suffolk Street, Birmingham, 1 (Jan. 31). An assistant chemist in the Royal Naval Cordite Factory, Holton Heath, Dorset—The Secretary to the Admiralty (C.E. Branch) (Feb. 3). A chief veterinary inspector for the Leicestershire County Council—The Clerk of the County Council, 10 New Street, Leicester (Feb. 3). A public analyst for the Metropolitan Borough of Fulham—The Town Clerk, Fulham, London, S.W.6 (Feb 7). A teacher of domestic science at the National Training College of Domestic Subjects, 72, Buckingham Palace Road, London, S W.1. A veterinary officer for the County Borough of Wallasey—The Town Clerk, Town Hall, Wallasey.

Erratum In the table on p 3 of Nature of January 6, the heading of the third column should be "Manual workers per 100 acres" and not "Manual workers per acre".

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

A Suggested Explanation of β-Ray Activity

IN continuation of our letter on the above subject which was published in NATURE of November 11, 1933, p. 747, we wish to add the following remarks:—

We have changed the term 'electrodivision of quantum' used in that letter to 'electrofission of quantum'. Under the intense electrical field of the nucleus, a quantum of sufficient energy undergoes *fission* into an electron and a positron, the energy being distributed between them in varying proportions, but the law of conservation of energy continues to hold good.

Our interpretation offers an unforced solution of Bohr's paradox that though the nucleus contains no electrons, free or bound, but only positive particles (α-rays, protons) and neutrons—a view which is now universally held—a β-ray can be created inside it and ejected with high speeds. It has further been established that radioactivity, whether marked by an α-ray or a β-ray disintegration, is mainly due to the leakage of loosely bound α-particles through the potential barrier. The β-ray is only a by-product, when the α-particle cannot escape, but on leaking to the second crater falls into a lower level, and gives rise to a γ-ray which undergoes fission into an electron and a positron.

We should further add that the phenomenon of 'electrofission' is different from the reverse process of annihilation of charges or conversion of radiant energy into mass postulated by many astrophysicists. For when a positron and an electron combine to form one or two γ-ray quanta, the charges do not neutralise but form a dipole which can be again disrupted into its constituents. This does not bring us nearer to the problem of the total conversion of mass to radiation, for the main amount of mass resides in the neutron, which according to one of us (Kothari) is a dipole formed of two Dirac magnetic poles of opposite sign, separated by a distance of e^2/Mc^2. The neutron evidently cannot be disrupted by the nucleus; the binding is too strong. It may be disrupted, however, by the electromagnetic action of cosmic rays, giving rise to free magnetic poles. Such phenomena, to our knowledge, have not yet been observed.

Much other evidence, physical as well as astrophysical, in favour of these views has been obtained.

Activities of Life and the Second Law of Thermodynamics

IN "The New Background of Science" Sir James Jeans, in discussing the activities of life in relation to the second law of thermodynamics, states that living organisms must possess some method of evading this law. He points out, for example, that a visitor to this planet from some other universe would observe various curious and highly improbable arrangements of matter, such as collections of gold in various places, numerous collections of ice in hot climates, etc. These improbable arrangements or organisations imply presumably a decrease of entropy, that is, a violation of the second law. Surely, however, these actions are functionally inter-related with other simultaneous actions; namely, the metabolism and oxidation of food by the human organisms and the oxidation of fuel in such engines as they employ, and these causally inter-related actions involve an increase of randomness, that is, disorganisation and consequent increase of entropy. I presume that Sir James Jeans would agree that the total effect will be a net increase of entropy.

An essential feature of the second law is that a finite amount of organisation may be purchased at the expense of a greater amount of disorganisation in a series of inter-related spontaneous actions. If for a single moment the blood sugar circulating through the brains of Sir James Jeans's humans should cease to be oxidised, they would fall down unconscious and cease to be able to collect gold or ice. Is it good logic to pick out a series of actions which imply an increase of organisation and therefore a decrease of entropy, whilst neglecting simultaneous interlocked actions in the same system which involve a greater increase of entropy, and then to announce as a mysterious result that the former actions evade the second law? Could one not reason in a similar manner that a crystal evades the second law when we watch a crystal growing in a supersaturated solution? No doubt the growth of the crystal involves *per se* an increase of organisation, but this increase is purchased at the expense of a greater decrease of organisation in the inter-related actions, as may very readily be demonstrated. Such examples in inorganic Nature can be multiplied almost *ad infinitum*.

I do not wish to assume the rôle of a die-hard *fidei defensor* of the science of the nineteenth century, or to assert or even suggest that the present known principles of science suffice to offer an adequate description of the phenomena of life. Indeed, in various publications I have striven to show that such an opinion or assertion would be quite unjustified. Nevertheless, I would humbly suggest that eminent physicists must not ignore the known and relevant facts of biochemistry, and that a knowledge of these facts may serve to remove a certain amount of mystery from their minds.

Artificial Production of the Blue Fluorescence of Fluorite

CATHODO-LUMINESCENCE, thermo luminescence and phosphorescence of fluorite show the well-known rare earth lines. These are, as a rule, not conspicuous in the *fluorescence* excited by filtered ultra-violet light, except in certain cases, especially when the concentration of the rare earths is high, as in yttrofluorite and yttrocerite, but also in some ordinary fluorites, especially after suitable heat treatment.

Generally the fluorescence shows only three diffuse bands in the red, green and blue-violet, differing also in their behaviour towards temperature. As has been shown previously[1], the capacity to emit these bands, the well-known blue one included, can be destroyed by heating and regenerated by treatment with radium rays (radio-photofluorescence).

Systematic experiments with synthetic materials, kindly prepared for us by Miss E. Rona, have proved that the element responsible for the blue band is a rare earth, most probably europium Pure CaF_2, and CaF_2 with additions of one per mille Ce, Pr, Nd or Sm, do not show, after heating and exposure to radium rays, the blue band when examined visually with ultra-violet light; CaF_2 with Sm containing traces of Eu show it distinctly, with pure Eu very strongly, with Gd weaker, with Tb, Dy, or Ho not perceptibly With one per mille Eu and suitable heat treatment, we obtained preparations that fluoresce, after radium treatment, with purple light; prolonged ultra-violet illumination destroys the red band and the preparation then emits a beautiful blue light, which, in intensity and colour, exactly matches the fluorescence of the best English fluorites Spectrograms of the fluorescence of such a natural fluorite (Weardale) show, after sufficiently long exposure, amongst other lines, several coinciding with europium lines Also when the preparations are diluted to one-tenth per mille the one containing Eu gives the greatest intensity of the blue band

A more detailed report will be presented to the Vienna Academy of Sciences in due course, when the influence of the other rare earths and of their concentration have been examined

Interpretation of the Benedicks Effect

ACCORDING to Benedicks[1], thermoelectric forces should exist even in a homogeneous substance, if only the gradient of temperature is asymmetrically distributed. For example, a potential difference should occur at the ends of a homogeneous wire when both are kept at the same temperature, if a point in between is heated in such a way that the decrease of temperature takes place in a much shorter interval at one side compared with the other The ordinary theory of conduction leads to effects which depend on the total temperature difference only and not on the length of the interval. Considerable doubt[2] has been expressed, therefore, as to the reality of this Benedicks effect. By quite a simple macroscopic consideration, however, its existence can be demonstrated and also its maximum magnitude in a limiting case can be derived

The conditions for the Benedicks effect must be such that the assumptions of the ordinary theory of conductivity cease to be valid The only possibility for this, so far as I can see, consists in gradients of temperature so high that a considerable variation of temperature (compared with temperature itself) occurs in an interval short compared with the mean free path *l* of the electrons

A general theory for this case seems to be extremely difficult, but one may hope for simplification in the limiting case of a sharp jump of temperature (with a breadth small compared with *l*). Even this offers still a rather complicated problem, as the distribution function for the electrons near the discontinuity is influenced by the neighbourhood of the material with a different temperature and is not simply the distribution calculated in the ordinary way for a homogeneous material. (In the case of a contact of two different materials at the same temperature, it can be easily shown that the distribution is not disturbed, the ordinary theory remaining valid therefore) It is only if the 'back diffusion' of the electrons returning from the other side of the discontinuity can be neglected, that conditions become more simple, as the distribution remains the ordinary one up to the contact itself.

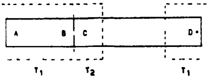

FIG 1

This can be arrived at in two ways. Either the dimensions of the contact are to be small compared with *l* (so that we have, say, a hole, as in the Knudsen effect), or an intermediate layer (for example, a potential barrier of some sort) is present, which reflects the greater part of the impinging electrons, transmitting a small fraction only Such a hole conforms to a degree to the usual experimental conditions, as the cross-section of the contact is kept as small as possible to obtain a high gradient of temperature.

Consider, therefore, a 'Benedicks chain' as in Fig. 1, with a sharp jump of temperature and a suitable contact (hole or barrier) between the points *B* and *C*. The potential difference φ_B between the points *A* and *D* (kept at the same temperature, T_1) consists then of two parts:

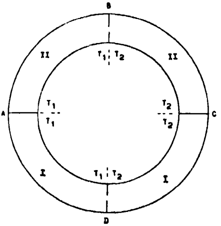

FIG 2

$$\varphi_B = \varphi_D \Big|_{T_2}^{T_1} + \varphi_T \Big|_{T_1}^{T_2} = (\varphi_D - \varphi_T) \Big|_{T_2}^{T_1}; \qquad (1)$$

φ_D at the discontinuity and φ_T of the slow gradient between *C* and *D* The equilibrium condition (if one neglects the 'back diffusion') consists then simply in the equality of the numbers of electrons transmitted from both sides of the discontinuity. As the number of incident electrons on a surface increases with temperature, a potential difference must be built up, which retains the surplus from the hotter side. (It is assumed that the distribution function is not changed appreciably by the space charge, which, for good conductors, certainly is justified.)

In order to calculate φ_B, consider a chain as in Fig. 2 with two opposite jumps of temperature in two different materials. This chain does not give rise to an E.M.F. As, with our assumption, simple differences of currents from both sides have to be considered at all contacts, one can remove intermediate links without disturbing the balance. At this point it is essential to neglect the back diffusion, as, otherwise, the numbers of electrons outgoing from both ends of the link A–B will not be the same. Furthermore, one has to assume that the number of electrons for unit surface, which are retained by a given potential difference, does not depend appreciably either on temperature or on the nature of the metal. This condition is fulfilled, if the electrons are in a state of high degeneration, that is for all ordinary metals.

If we transpose in the above sense the 'hole' at B to the contact at A, and D to C, a symmetrical arrangement remains (one metal at T_1, the other one at T_2, and at both contacts a sharp jump of temperature) and, therefore, neither chain (the transposed or the original one) can give rise to any current.

If we substitute in the original chain a slow transition of temperature in solid material for the sharp discontinuities at B and D, there remains simply an ordinary thermocouple with a corresponding E.M.F. $F_{\mathrm{I,II}}$. If we write down this balance we obtain the relation:

$$0 = F_{\mathrm{I,II}} + \left(\varphi_D \Big|_{T_2}^{T_1} - \varphi_T \Big|_{T_2}^{T_1}\right)_{\mathrm{II}} - \left(\varphi_D \Big|_{T_2}^{T_1} - \varphi_T \Big|_{T_2}^{T_1}\right)_{\mathrm{I}} \quad (2)$$

or with (1)

$$- F_{\mathrm{I,II}} = \varphi_{B\mathrm{II}} \Big|_{T_2}^{T_1} - \varphi_{B\mathrm{I}} \Big|_{T_2}^{T_1}. \quad (3)$$

Now, the E.M.F. of a chain can always be written as the difference of two functions characteristic for each of the two constituents

$$F_{\mathrm{I,II}} = F_{\mathrm{I}} \Big|_{T_2}^{T_1} - F_{\mathrm{II}} \Big|_{T_2}^{T_1}, \quad (4)$$

and we obtain, therefore, by comparison with (3), the general result:

$$\varphi_B \Big|_{T_2}^{T_1} = F \Big|_{T_2}^{T_1}, \quad (5)$$

that is, the potential of our special Benedicks chain is a magnitude which can be described as an absolute thermoelectric potential for a single material. It is, therefore, of the same order of magnitude as ordinary thermoelectric potentials.

It is to be noticed that the above result, though independent of any special model, is only valid for a suitable contact and a sharp discontinuity of temperature. It represents clearly the maximum effect possible. But as, according to our present picture, the free path comes out rather large, especially for low temperatures, where it reaches macroscopic dimensions, it should not be impossible to measure this effect.

A more complete discussion, together with a kinetic derivation and a treatment of related subjects, will shortly appear in the reports of the Réunion Int. de Chimie-Physique, Paris, 1933 ("Act. Sci. et Ind.", Paris, Hermann) and the *Nachr. Goett. Ak. Wiss.*

Institut Henri Poincaré, **LOTHAR NORDHEIM.**
Paris.

Chemistry of Cheddar Cheese-making

SINCE its introduction by Lloyd in 1895 in the south-western counties of England, the determination of the acidity of the whey exuding from the curd has been regularly used by cheese-makers as a means of timing the manufacturing operations. The acidities are generally expressed as percentages of lactic acid in the whey. During the later stages of the process, it is found frequently that there is a fall in acidity in the whey, more especially after the salt has been added. No valid explanation has been put forward for this fall in acidity, apart from the obvious ones, namely, that the whey after salting is diluted with fat and salt, and the acidity might be expected to fall.

Determination of lactic acid in the wheys at various stages in the Cheddar cheese-making process have shown that there is a steady and continuous rise in the percentage present, even through the salting stage, despite the fact that the titratable acidity at this latter stage either falls or shows no appreciable rise. The rise in lactic acid content is accompanied by a very marked rise in calcium content (already noted by Lloyd) and the lactic acid is carried out in the whey as calcium lactate which does not exert any appreciable buffer action at hydrogen ion concentrations intermediate between the normal hydrogen ion concentration of wheys and the phenolphthalein end point.

Determination of the lactose content of whey has shown that there is a sharp fall in the percentage of lactose in the water of the whey liberated by the addition of salt at the salting stage. This is due to a diffusion outwards of water from the curd, and probably to a liberation of bound water from the curd. The addition of salt to curd at any of the earlier stages of the cheese-making process produces a similar sharp fall in the lactose content of the whey, calculated on the basis of the water content; whereas the whey from the unsalted curd shows a steady fall in lactose content. That rennet curd contains a considerable quantity of bound water is indicated by the fact that the proportion of lactose to water in the whey immediately after the curd is cut is greater than the proportion in the original milk, indicating that about 2 per cent of the water in milk is bound, that is, cheese curd will contain a quantity of bound water equal to about four fifths of its casein content.

An attempt to throw some light on the action of salt on cheese curd has yielded interesting results. Sodium sulphate was added to milk to give a concentration of 0·1 per cent SO_4 radicle. The proportion of SO_4 to water in the whey showed a slight fall until the salting stage was reached, after which there was a sharp rise of about 50 per cent, despite the fact already referred to above, that there is a dilution of the whey either by osmosis or by the liberation of bound water. No well-founded explanation is submitted for this observation, but it is suggested that the curd may be acting as a membrane and that the rise in SO_4 content is a Donnan equilibrium effect.

These matters are receiving further attention at this Institute.

Condensation of Water in the Atmosphere

IN NATURE of December 16, p 938, it is stated "A number of workers, notably Defant, Köhler, Niederdorfer, claim to have shown that the volume of droplets in the atmosphere are most frequently integral multiples of some standard minimum size" The "law" claimed by Defant and Köhler is much more interesting than this statement implies.

In 1905 Defant measured raindrops : the smallest drops were less than 1/40th of a milligram in weight, while the largest were more than 100 milligrams.

The outstanding feature of the result which Defant claimed to have established was that the most frequent sizes (weights) of raindrops were in the ratio 1 2 · 4 8 16, etc. Defant found two such series In the principal series the unit was 0 115 mgm , and in the secondary series it was 0 35 mgm or three times as heavy Thus the two series can be represented as $1x$, $2x$, $4x$, $8x$, etc and $3x$, $6x$, $12x$, $24x$, etc where x is 0 115 mgm This immediately suggests three things

(i) Primary drops tend to be of the same size

(ii) Large drops tend to be formed by coalescence of drops rather than by continuous growth.

(iii) Gravity is an effective operating agent in the formation of compound drops

If one had (i) and (ii) alone, then drops would tend to be 1, 2, 3, 4, etc , times the primal drop ; that is, the integral multiple law would hold. The "law of 2" necessitates a sorting of the drops by the action of gravity. Such a sorting by gravity is indeed inescapable rain does fall on places not themselves in cloud I remember mentioning this twenty five years ago in a letter to the late Prof. Poynting about his note on the rate of fall of cloud drops in the first edition of the volume on "Heat" in the Text Books of Physics series, and in later editions he referred to Defant's work

These measurements by Defant were made with raindrops Kohler, many years later, measured the sizes of drops in fogs and clouds, and came to the conclusion that for these drops, also, the same "law of 2" held Those drops have a diameter 100 times less than Defant's raindrops, and weights 1,000,000 times less[1]. At that time I wrote . "Independent testimony—dare one hope from Scotland—is required of the 'law of 2' before it can be included among the established facts of meteorology". It appears from the article in NATURE of December 16 that not only does Scotland stand where it did, but that the testimony is not yet complete

Measurements of Submarine Daylight

IN the course of the last nine years Poole and Atkins[1] have developed a very ingenious method for measuring the intensity of the daylight penetrating into the sea by means of alkali-metal photo-cells, using a delicate balance method for measuring the very weak photo-currents. The many vagaries of the photo-cells make measurements with this contrivance rather difficult to any but trained experimenters In order to find a simpler and less expensive method of measuring submarine daylight we have used the novel 'Sperrschicht' selenite photo-cells due to Dr B. Lange. As these cells give a photo-current several hundred times more intense than the most sensitive of the alkali cells, it is possible to use an ordinary pointer galvanometer, or some similar instrument, for the observations, while at the same time they are simpler and more easily manipulated by relatively untrained observers. The instrument used for our measurements gave a deflection of one scale-unit for 3 76 × 10^{-7} amperes and could be read to within 0 1 scale-unit. Another advantage of the Lange cell is its broad maximum of sensibility between 4500 and 5500 A., that is, with its centre near the minimum of light-extinction found by Knudsen for coastal water at 5100 A. The narrow region of maximum sensibility characteristic of the potassium cell is situated much nearer the violet end of the spectrum

We have been using the Lange cell, protected from the water by a thick disc of plate-glass, externally roughened, within a strong box of brass, into which a rubber-insulated cable holding two 0 75 mm.^{2} copper wires for the photo-current passes from below Readings taken, first when the instrument was being lowered into the sea, then repeated at the same depths while it was being raised to the surface, agreed closely *inter se* and showed characteristic variations in the transparency, apparently due to plankton or to detritus suspended in the water On a clear day in August the submarine daylight in the central Baltic Sea could be measured by this simple contrivance down to a depth of 50 metres. With the cell inverted, its sensitive surface facing downwards, the light scattered upwards could be measured down to 25 metres.

Two similar instruments combined with a registering galvanometer have for the last three months been used for recording continuously the variations in submarine daylight in the Gullmar Fjord, here suspended from our observation pier, one in 15 metres depth and the other cell one metre below the surface. We believe the instrument will become useful to oceanographers for making rapid surveys of the transparency of the water at different depths and also for studying the relationship between the light-factor and the flowering of the phyto-plankton. A more detailed report is being published in *Meddelanden från Goteborgs Högskolas Oceanografiska Institution*

Structure of Collagen Fibres and the Point of Attack by Proteolytic Enzymes

SOME recent work by Bergmann and his colleagues has shown that the action of trypsin on gelatin gels is limited to the surface of the gel[1] and that the action on fresh collagen fibres is limited to the cut ends of the fibres[2], the enzymes having apparently no power to attack the fibres from their sides. Some observations made here on the penetration of bacteria into putrefying hide suggest that the same generalisation can be applied to the bacterial proteases.

It has been observed that the organisms penetrate the experimental pieces most readily from their cut edges and from the inner or 'flesh' surface, penetration from the outer or hair surface being very slow. According to Kaye[3], the reticular fibres of skin, which hold the collagen fibres and fibre bundles together, are readily attacked by bacteria. Bacterial penetration between the collagen fibres can occur therefore through the hydrolysis of the reticular fibres

A microscopical study of the penetration of bacteria suggests, however, that the sides of the collagen fibres have considerable resistance to the action of the proteolytic enzymes of bacteria. It is well recognised that keratins are resistant to proteolytic enzymes and the resistance of the hides to penetration of bacteria from the hair surface is doubtless due to the keratinous outer layers of the epidermis It was recently observed, in examining a consignment of hides from Kenya, that putrefaction commonly occurred along brand marks and cuts on the flesh surface caused by bad flaying, even when the rest of the hide was free from any sign of taint. The putrefactive bacteria evidently gained access into the hides at the cut ends of the fibres on the flesh side and through the epidermis where it had been thinned and changed in character as in the regeneration that follows after burning, that is, in the condition found in a brand mark The fact that the brand marks had been denuded of their protecting hair may also play some part in the greater tendency of these parts to putrefy—more organisms having possibly been deposited on them during the curing process. These hides were a consignment cured under experimental conditions through the co-operation of the Government of Kenya and the Imperial Institute, by the courtesy of which we were able to examine them

The suggestion that proteolytic enzymes can attack collagen fibres with ease at their cut ends, but only with difficulty at their sides, is in accord with the molecular structure of collagen fibres recently suggested by one of us[3]. It is also in accord with the demonstration made by Marriott[4] that the shearing strain of the cutting tool alters the character of the collagen, making it take on the properties of gelatin This change can now be interpreted as due to a change in molecular structure rather than chemical nature.

Mr. H. R. A. Mallock, F.R.S.

THE obituary notice of the late Mr. Mallock in NATURE of January 6 refers to his experiments on the trajectories and extreme range of rifle bullets. It was in 1896 that I began an association with Mr. Arnulph Mallock which continued actively until his health failed a few years ago. He was always interested in rifle matters as well as in big guns, and first came to me at the suggestion of the late Sir Henry Halford, whom he knew through Mr W E. Metford, to consult me as to an optical rifle sight which he had devised. Together we made at various times many experiments, such as one on the rate of increase of the velocity of a bullet when fired ; a ballistic pendulum was used and the barrel was cut down by stages. In connexion with questions of air resistance, he also carried out trials with bullets having a velocity as high as 4,000 ft. per sec., using for this purpose a special cordite and a bullet of spherical shape

The notice in NATURE mentions Mallock's work in ascertaining the extreme range reached by rifle bullets, about which no great certainty existed, by a new and successful method It was in 1910 and 1911 that, by the kindness of Sir Andrew Noble, we were enabled to fire into the water parallel to a long stretch of shore on Loch Fyne, Mallock with other observers taking up positions approximately opposite the point at which the bullets fell into the water when fired with increasing angles of elevation. It had been thought that in calm conditions—for calm was in any case essential—the splash made by the bullet would be visible, but beyond 2,000 yards it could not be seen However, the 'plop' of the bullet as it struck the water could be heard, and it was found by all who assisted that its direction could be located with unexpected accuracy and plotted in relation to the opposite shore half a mile away. In this way groups of shots were mapped. Shooting was done on five days in the very early mornings, and the 0 303 in. rifle was fired with different loads, and also the 0 280 rifle, up to extreme range. It was found that with the present pattern of 0 303 Service cartridge (Mark VII), then newly adopted, the extreme range was 3,400-3,500 yards, the height reached by the bullet being about 3,500 ft. and the time of flight about 28 seconds. The angle giving the maximum range was a little more than 30°, firing with angles of 35° and 40° showed the shortening of the range. The method of firing into water for long range trials has since come into use in Great Britain and elsewhere.

Mallock, in the years before his marriage, habitually worked through the night at his laboratory in Victoria Street, to avoid interruption. There were a surprising number of directions in which he applied his great knowledge, which was always at the service of others. It may be worth noting that he always firmly believed the helicopter to offer the final solution of the problem of safe and practical flying. He had great musical gifts, and an amazing memory, which made his conversation full of interest.

Leonids Observations from an Aeroplane

THE weather conditions in November 1933 being unfavourable, it was decided by the United Czechoslovak Observatories, (National Observatory, University Observatory, Stefanik Observatory) to use an aeroplane for observations of the Leonids

Opportunity was given by the Czechoslovak Government and the Public Airlines Company to provide a three-engined Fokker for meteor observations. According to C. C. Wylie, in *Popular Astronomy*, 41, p. 170, the maximum was to be expected in the night of November 16–17. On this date the night was thoroughly cloudy and all preparations for the flight being made, the Fokker left the airport of Prague at $1^{h}\ 30^{m}$ (M.E.T.). There were three observers : Dr. E. Buchar, Dr. V. Guth, Dr. H. Slouka, one assistant, Mr. Bláha, the pilot and the radio-operator. The first observations were made at a height of 1000 m. but growing clouds and mist forced the pilot to ascend to 3000 m. The view of the observers was somewhat limited by the wings; Dr. Guth, who was at the rear window of the aeroplane, had the best view The windows were open and the fields of view were estimated in square degrees

The following observations were made

Nov 17 Time 1 30 2 30 (M E T)

Observer	Field of view in square degrees	No of meteors	No of Leonids
Bláha	1000	2	2
Buchar	1200	5	5
Guth	2500	12	10
Slouka	1200	4	3

Contrary to expectation, this year's Leonids were decidedly few, or the maximum was shifted a few hours or days and was not observed because of bad weather

The usefulness of aeroplanes for meteor observations was proved beyond a doubt, and preparations are being made for the modification of an aeroplane so that the observers will have an unlimited field of view HUBERT SLOUKA.

External Leaf-Characters of the Cricket-Bat and other Willows

IN a recent paper, Dr J Burtt Davy gives photographs showing the size and spacing of 'surface dots' on the upper side of the leaves of *Salix alba* L, *S. fragilis* L and × *S. viridis* var *elegensis*[1] It has been suggested that these surface dots, which occur in willow leaves generally, may be of diagnostic value in determining the true cricket-bat willow, *S alba* var *cærulea*, Smith; and an investigation of this feature has accordingly been undertaken.

The 'surface dots' represent *stomata*, which in willow occur on the upper as well as on the lower surface of the leaves, and it must be fully recognised that the evidence of many independent workers indicates that there is no diagnostic value in the size of stomata, or in their number per unit area of the leaf[2]. Such, in general, after an examination of a large number of leaves, is my own conclusion with regard to the various species of willow

It is, however, possible that if completely comparable mature material of different species and varieties, grown under exactly similar conditions of soil, water-supply and exposure to light and air, could be used, rough estimates of stomatal frequency might be made with the aid of a good lens, which might be of some help in diagnosis From an examination of such comparable material, *S alba*, for example, was found to have roughly twice as many surface dots as *S fragilis* Actual counts of the number of stomata per square millimetre were made by removing the epidermis from leaves by means of a weak macerating agent, and examining microscopically The counts were most probably comparable, for the material was treated in the same way in the different cases, and was in the same condition before treatment; they gave an average of 114 per sq. mm. for *S. alba*, and of 50 for *S. fragilis* It must not be concluded, however, that 114 and 50 represent the *actual* number of stomata per sq. mm when the epidermis was in position on the leaf; for the area of a *detached* portion of epidermis is not necessarily the same as when held in position by the underlying leaf-tissues; epidermis may shrink or stretch when removed, according to the condition of the underlying tissues

Unfortunately, surface dots did not provide a diagnostic difference between *S alba* and var *cærulea* in the comparable material examined, for the number was approximately the same in the two cases (113 per sq mm in var *cærulea*). Dr. Burtt Davy notes that Dr. Floderus, of Stockholm, is unable to recognise var *cærulea* as distinct from *S alba*[3], it was certainly not decisively differentiated by the frequency of the stomata in the leaves for which counts were made Further, it must be noted that surface dots do not provide a reliable means of distinguishing × *S viridis* var *elegensis* from *S. alba* in the field

Mention may also be made of the hairiness of the surfaces of old leaves of *S. alba* and var. *cærulea*. It is frequently stated that such leaves of var *cærulea* are glabrous on the lower side, and that they are thereby distinguishable from those of *S alba* They were, however, found not to be consistently glabrous, var *cærulea* is thus not certainly distinct from *S. alba* in this character also, for, like the spacing of stomata, hairiness is a surface feature varying with external conditions

These notes are contributed by way of warning field-workers on the bat-willow problem that external leaf-characters do not provide consistent and reliable diagnostic data unless used with extreme discretion.

The Term 'Mesolithic'

I HOPE I may be allowed to call myself an archæologist, although a very humble one, yet I find myself in complete disagreement with my friend Mr Reid Moir in NATURE of December 30, p 1006. After C. J. Thomsen[1] had in 1836 revived the idea of Lucretius[2] and divided the past history of man into the three ages of stone, bronze and iron, there was one stone age, but when the discoveries of Boucher de Perthes had been recognised by English savants, Sir John Evans[3] in 1859 pointed out that this age must be divided into two, that in which the *fauna* was extinct and that in which it was recent. Later on, Sir John Lubbock[4] suggested that these two periods should be termed respectively the palæolithic and neolithic ages. It was soon noted, however, that these ages did not pass into one another, but that between them there was a great gulf fixed, and this became known as the great hiatus

About the same time an opportunity occurred to bridge this gulf, for in 1860 Profs. Steenstrup, Forchhammer and Worsae were appointed a committee to investigate the shell-mounds that had recently been discovered on the shores of Jutland[5]. These savants differed as to where this culture was to be placed, for, whereas Worsae suggested that these remains should be relegated to a late phase of the Old Stone Age, Steenstrup allotted them to the true Neolithic Age To effect a compromise, Lubbock suggested that these remains should be referred to an early Neolithic period[6], in which they remained for many years.

By degrees other industries were found which could neither be placed in the Old Stone Age or the

New, and matters came to a head with the discovery of the deposit in the cave of Mas d'Azil, first explored by Piette in 1887[7], and continued for several years. The study of these implements led him in 1895 to suggest that there was a transitional period between the Palæolithic and the Neolithic Ages[8] He had, however, been anticipated in this, for on March 8, 1892, Mr John Allen Brown read a paper before the Anthropological Institute, postulating the existence of a Mesolithic Age[9]

The paper by Piette, the remains from the cave of Mas d'Azil, the microlithic industry found by E Vielle in 1879 in the park of the Chateau of Fère near Fère-en-Tardenois[10], and the early culture found in 1903 by Sarauw at Maglemose[11], persuaded the archæologists of France to insert a transitional phase between the Old and the New Stone Ages. This was clearly set out by Déchelette in 1908[12], though in deference to the views of the Danish archæologists he excluded from this phase the culture of the shell-mounds, which he left standing alone in an early Neolithic Age This treatment was followed by Sollas[13] in 1911 and 1924, and by Burkitt[14] in 1921, but in the latter year Macalister[15] boldly included the shell mound culture in a period that he called Mesolithic

The advantages of this new arrangement seem obvious Palæolithic remains are found associated with an extinct *fauna* and glacial or interglacial environments True Neolithic remains are associated with agriculture, domesticated animals, pottery and ground or polished implements There are, however, cultures that have neither kind of association and lie for the most part between the two others in time What more natural than to treat them as a series apart and call them Mesolithic ?

At first some writers, notably Gordon Childe[16], feeling that these cultures were really rather an appendix to the Palæolithic Age than an entirely new phase, used for them the term Epipalæolithic, a name first introduced by Obermaier in a slightly different connotation It is undoubtedly more logical, but Mesolithic has the advantage of being shorter and so has won the day At last, after a struggle of nearly forty years a Mesolithic Age has been adopted by all archæologists except Mr Reid Moir

Influence of Pressure on the Spontaneous Inflammation of Hydrocarbons

NEARLY a year ago we investigated the conditions of spontaneous inflammation in mixtures of pentane and oxygen at pressures from 5 cm to 140 cm by admitting the gases into an evacuated metal vessel. We were not satisfied with the data obtained, since the experimental points showed considerable scattering, and the work was therefore not published

The curves obtained by us for the mixture $C_5H_{12} + 8O_2$ in an iron bomb and in a bomb the inner surface of which was covered with gold (Fig 1) have sharp kinks in the region of 60 cm We were, therefore, able to draw the conclusion that there are two different ways in which the oxidation may proceed, each of which prevails in a definite region of pressure.

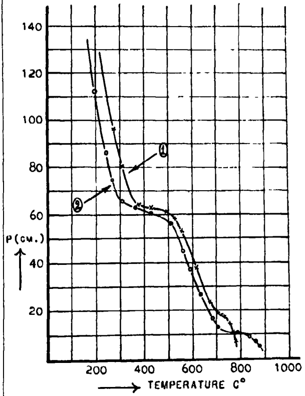

FIG 1 Pressure-temperature curves for spontaneous inflammation of the mixture $C_5H_{12} + 8O_2$ in (1) iron vessels, (2) gilded vessels

Townend and Mandlokar[1] have recently investigated the inflammation of butane-air mixtures and have found that the curves have distinct breaks in the pressure region between 1½ and 3 atmospheres. They explain this fact on Bone's hydroxylation theory .

$$\begin{array}{ccccccc} R\,CH_3 \rightarrow & R\,CH_2OH & \rightarrow & R\,CHO & \rightarrow & R\,COOH & \rightarrow \text{etc} \\ & \downarrow & & \downarrow & & \downarrow & \\ \overline{RH} + & CO & \overline{+ H_2} & \overline{RH} + & \overline{CO} & \overline{R\,OH} + & \overline{CO} \end{array}$$

At high pressures, ignition probably arises as the result of the rapid oxidation of an aldehyde or other intermediate oxygenated product which may occur at temperatures of about 300° C.; at low pressures, conditions are more favourable to the thermal decomposition of these bodies into hydrogen, carbon monoxide, methane, etc., the ignition of which does not occur until much higher temperatures have been attained.

This hypothesis finds support in work carried out at the Leningrad Institute of Chemical Physics. Thus Kovalsky[2] has found that at low pressures the oxidation of methane is accompanied by the formation of carbon monoxide in large quantities. Sadovnikov[3] has recently shown that at low pressures, during the inflammation of ethane-oxygen mixtures, carbon monoxide accumulates and then explodes.

From our own experimental results, we are able to apply the above hypothesis, used for butane mixtures, to pentane mixtures. The existence of a sudden lowering of the inflammation temperature at any critical pressure may therefore be considered to be quite general for the inflammation of complex hydrocarbons.

It is possible that this fact is closely connected with the increased probability of knock with increase of compression ratio in internal combustion engines.

Raman Spectrum of Heavy Water

THE Raman spectrum of 80 per cent heavy water obtained with a sample supplied by Prof. H. S. Taylor of Princeton, when compared with the spectrum of the 18 per cent material previously reported[1], shows that the water molecule with two atoms of heavy hydrogen gives a Raman band with a frequency difference of 2517, while the molecule with one atom of heavy and one of light hydrogen gives *two* bands, one of frequency difference of 2623, the other of 3500. Ordinary water gives a band with frequency difference 3445. A single photograph of a sample of given concentration does not bring out this shift as the bands overlap; but by superposing the *two photographs taken with different concentrations*, the shift in the centre of gravity of the bands comes out in a very striking manner.

Preparations have now been made for photographing the spectrum of the vapour, in which case we shall doubtless find double lines in place of the superposed and slightly shifted bands.

Molecular Polarisations of Nitrobenzene in Various Solvents at 25° C.

A STUDY of the dielectric constants, densities and refractivities of dilute solutions of nitrobenzene in various solvents at 25° C. has been made in these laboratories with the following results:

Solvent	ε	$_\infty P_2$ c.c.	$_\infty P_{A+O}$ c.c.	μ
n-Hexane	1·887	372·5	339·9	4.049×10^{-18} E.S.U.
cyclo-Hexane	2·016	360·0	327·4	3·974 ,,
Dekalin	2·162	352·9	320·3	3·930 ,,
Carbon tetrachloride	2·228	353·1	320·5	3·932 ,,
Benzene	2·273	353·8	321·2	3·936 ,,
Carbon disulphide	2·633	310·0	277·4	3·658 ,,
Chloroform	4·722	241·2	208·6	3·172 ,,

$_\infty P_E = 32.6$ c.c.

where: ε = dielectric constant of solvent, $_\infty P_2$ = total polarisation of nitrobenzene at infinite dilution, $_\infty P_{A+O}$ = atom + orientation polarisation, $_\infty P_E$ = electron polarisation, and μ = apparent electric moment calculated from the Debye equation neglecting the unknown atom polarisation. The error of measurement of the polarisations is probably ± 0·5 c.c.

If $_\infty P_2$ for all these solvents is plotted against ε, a reasonably straight line is obtained, the polarisation of the solute falling with increasing dielectric constant of the solvent. It is to be noticed that the table contains a polar solvent, chloroform. Non-polar solvents have dielectric constants between 1·8 and 2·6 approximately, and possibly polar solvents of higher dielectric constants may prove as serviceable for the measurement of apparent dipole moment as non-polar ones. The right conditions for the accurate determination of the dipole moment of a molecule in solution has yet to be found. In the past the Debye equation deduced for a gas has been slavishly applied. It may not be valid for a solution.

A more detailed account of this work will be published later.

Integral Right-angled Triangles

IN NATURE of September 9 and October 14 integral right-angled triangles have been discussed. It is of interest to note that in the general solution

$$2fg, \quad f^2-g^2, \quad f^2+g^2,$$

if we make f and g consecutive terms of the series

$$1, 2, 5, 12, 29, 70 \ldots$$

where $U_n = 2U_{n-1} + U_{n-2}$
we get triangles whose sides about the right angle differ by unity.

The first five triangles are

4	3	5
20	21	29
120	119	169
696	697	985
4060	4059	5741

The first one is used extensively by surveyors and others when constructing a right angle either on the ground or on a plan. The second, however, is a better 'conditioned' triangle and would be used if it were more generally known.

The law of formation of the series given above is the same as the law for forming successive convergents of $\sqrt{2}$ from the continued fraction.

Successive approximations to $\sqrt{2}$ can be obtained by dividing the hypotenuse by the mean of the other two sides of the triangles given here. If we take the fifth triangle and divide 5741 by 4059·5, we get $\sqrt{2}$ correct to one part in a hundred million.

Research Items

The Capsian Industry. A preliminary reconsideration of the Capsian phase of the Stone Age in North Africa is put forward by M. R Vaufrey in *L'Anthropologie*, **43**, Nos. 5–6 in the light of the results of investigations in the shell-heaps of southern Tunisia in 1931–32 The evidence then collected gives an entirely different view of the Capsian industry from that generally accepted, according to which the Capsian is regarded as the ancestor of the Upper Palæolithic and the Mesolithic of Europe, and an upper and lower Capsian are distinguished, microliths being rare in the latter, the older culture. These investigations, which have been conducted in accordance with a more stringent method than that employed by previous investigators, show that the conception of an ancient Capsian composed almost exclusively of large implements is entirely due to an incomplete view of the evidence. More exacting methods of investigation show that *the microlith is abundant in this early stage*, and is already highly developed The Capsian, it appears, is *essentially one*, but is divisible *into three* chronological stages—a homogeneous body in which the microlith forms the binding material The three stages are typical Capsian in which points, burins and scrapers occur with a typical microlithic industry , (2) interogetulian neolithic or upper Capsian, in which the burin becomes exceptional, though scrapers are more or less numerous, while among the microliths, triangles and scalene points predominate, but true geometrical forms are rare, geometrical forms, however, characterising a divergent development in Algeria ; (3) neolithic of Capsian tradition, in which shell heaps are rare, the characteristic Capsian implement, the point *à dos rabattu* disappears, and evidence of Saharan influence appears Typologically the Capsian is late Palæolithic or Mesolithic, and does not belong to geologically ancient deposits. Hence it could not be the ancestor of Aurignacian, nor does it lend support to the African origin of *Homo sapiens*

Maya Archæology in South-West Guatemala In 1932 Mr and Mrs S. K. Lothrop made a reconnaissance of some thirty sites containing ancient remains and excavated the ruins of Chukumuk and Chuitinamit on the shores of Lake Atitlan in south-west Guatemala, a region archæologically almost unknown. In a report on the excavations ("Atitlan" Pub No. 444, Carnegie Institution, Washington) it is stated that the remains may be classified into several stylistic and chronological categories, and exhibit both strongly developed local characteristics and connexion with other areas Thus the most ancient types of pottery embrace non-Mayan elements which may have come from south and east ; but it is premature to decide whether it represents a transitional pre-Mayan population or a primitive Maya. The second pottery period shows connexion with 'early' Mexican culture as represented by Ticoman. It is related to late phases of Maya Old Empire as exemplified in Peten, western Salvador and western Honduras. At the same time it preserves non-Mayan elements of the previous schools. The last pottery period is typified by styles found at other highland sites such as Utatlan. As a whole, it has little resemblance to finds in other regions It is believed to cover the period of the political ascendancy of the historic highland tribes and ended with the Spanish conquest. Architectural features do not accord with those of other Maya remains. Ruined residences are of two kinds, which, it is believed, are of different epochs. As a whole, the remains indicate the early period in which the inhabitants drew inspiration from western Salvador and to a less extent from Central Mexico At a later period they were in contact with the Maya Old Empire, and in the centuries before the conquest developed a culture of strongly local type.

Di-iodothyronine in Myxœdema Although dried thyroid gland is physiologically active by mouth, the pure active principle, thyroxine, only exerts a comparable effect when given by injection it is generally supposed that this is due to failure of absorption from the gut, since thyroxine is very insoluble In the digestion in the intestine of the iodothyreoglobulin of the gland, a peptide of thyroxine is set free which is much more soluble than thyroxine itself, and so is readily absorbed The synthetic production of such a soluble peptide, however, has not been successful A derivative of thyroxine which exerts a significant amount of thyroid-like activity is 3 . 5-di-iodothyronine, which has the same structural skeleton as thyroxine but contains only two iodine atoms. Gaddum found that its activity was 1/15–1/40 that of thyroxine according to the method of test employed It is, however, more soluble than the latter, and this difference between the two compounds is still more marked in the case of their salts both with acids and alkalis The clinical value of the disodium salt in myxœdema has recently been investigated by A B Anderson, C. R Harington and D. Murray Lyon (*Lancet*, 1081, Nov 11, 1933) Daily doses of 50 mgm of the di-iodothyronine in water were given by mouth to six cases, and in each the basal metabolic rate was raised to, or nearly to, the normal level, the pulse rate was quickened and the weight was reduced when the patient was initially overweight. No toxic symptoms were observed with continued administration over periods of two to three weeks . on withdrawal of the drug, the metabolic and pulse rates fell and the weight rose again. The magnitude of the effects produced was similar to what might be anticipated from the daily injection of 1 mgm. of thyroxine Since di-iodothyronine can be prepared in the pure condition and moreover appears to exert its physiological activity with a remarkable degree of constancy, it may prove to be a valuable substitute for thyroid gland in all cases in which administration of the latter is indicated.

Structure of Larvæ of Hispine Beetles. An interesting case in which a study of the larval morphology has made it possible to correct the systematic position of the adult insect is offered by a recent paper of S Maulik (*Proc Zool Soc London*, 1933, part 3). The beetle *Platyauchenia latreillei*, Cast. has been referred to the subfamily Cassidinæ, but its larva lacks the prolongations at the end of the body which are used for carrying on the back of a mass of excreta, and constitute a character peculiar to larvæ of the subfamily Cassidinæ. On the other hand, the structure of the partially fused eighth and ninth segments of the abdomen is such as is often observed amongst larvæ of Hispinæ. Other larval and adult characters of *Platyauchenia* are discussed at length and it is concluded that the genus should be removed to Hispinæ At the same time the larva shows some modifications in the position of spiracles not previously recorded amongst Hispinæ, while its head, though that of a true miner, shows a structure different from any so far observed in other leaf-mining larvæ

Entry of Water into the Germinating Seed A study of the brief communication on this subject by Alexander Nelson and Jas C Macsween (*Trans and Proc Bot Soc Edin*, 31, Part 2) will dispel certain popular illusions The least study of the broad bean would show that the micropyle is far from being a hole permitting access of water to the interior of the seed, and careful measurements with beans floating in a 'lifebelt' of paraffin wax show that intake of water is about the same whether the half immersed includes the micropyle or not Reasons are given for concluding that two factors are at work in facilitating water entrance (1) the hydration of the colloids of the testa, (2) an osmotic action through the semi-permeable coat due to the release of carbohydrates in the inner lining of the testa Emphasis is laid in this paper upon the great variation in the behaviour of individual seeds

Growth of Evergeens According to the Science Service, Washington, D C, Prof Ansel F Hemenway, of the University of Arizona, has recorded evidence concerning the growth of the great evergreen trees of the Pacific north-west Prof Hemenway points out that the cambium, and also certain elongated cells, the function of which is considered by botanists to be the transportation of dissolved food substances, appear to be in active condition from early autumn until the commencement of the summer drought of this region In other words, that these species continue their growth throughout the winter Similar structures in deciduous or broad leaved species in the same region, and also in conifers and broad-leaved trees in Kentucky, do not appear to be functioning in specimens collected during the winter The Oregon broad-leaved trees also appear to have a period of little or no growth during the midsummer drought of the region It is thus apparent that there are two long periods in the year during which the broad leaved trees do not grow, whereas the evergreens are able to grow continuously through nine or ten months of the mild, moist autumn, winter and spring The author holds that the broad leaved species have lost the race for supremacy in the north-west coast region For this reason the forest of this region now consists almost entirely of Douglas spruce, grand fir, coast cedar and yellow pine

Geographical Distribution of Tea Cultivation Tea cultivation has a peculiar geographical distribution, *for apart from recent plantings in Africa and Russian* Georgia, commercial tea-growing is practically limited to the south-east of Asia and the adjoining islands, none being as yet carried on in America or South Europe The reasons for this have been recently discussed by H H Mann (*J Exp Agric*, 1, 245) The centre from which the plant originated, coupled with the availability of cheap hand labour, have naturally played an important part in the distribution of the crop as a commercial proposition, but despite these factors, the areas in which tea is grown are curiously limited. In certain directions the plant is very tolerant of variations in soil or climate, for it is found in comparatively temperate regions where frost is common and also in the neighbourhood of the equator In other respects, however, the crop are precise in its demands, certain conditions of soil and climate being essential for vigorous growth. Although most of the important tea estates lie on alluvial soils, the crop can be grown successfully on varied types provided certain physical and chemical conditions are satisfied In the first place, the soil must be deep and well drained, with a porous lower layer into which the roots of the plant can easily penetrate, and secondly, an acid reaction is essential, commercial success being unlikely if the *p*H is higher than 6 0 As regards manurial requirements the position is less clear Abundant available nitrogen is known to be important, but excessive quantities, particularly if not accompanied by adequate dressings of phosphoric acid and potash, prove harmful Recent work has, further, shown that other nutrients such as sulphur may sometimes be important, the diseased condition known as 'tea yellows' being attributed to a deficiency of this element

Long Beach Earthquake of March 10, 1933. The Californian earthquake of March 10, known as the Long Beach earthquake, is the subject of a valuable preliminary report by Mr H O Wood (*Bull Amer. Seis Soc*, 23, 43–56, 1933) Notwithstanding the great amount of damage caused in Long Beach and other towns, the shock does not belong to the class of great earthquakes, but was rather a fairly strong local shock originating near a thickly populated region From the records obtained at seven stations in southern California, the epicentre was found to be in about lat 33° 34 5′ N, long 117° 59′ W, or 3½ miles south-west of Newport Beach and in the general course of the Inglewood fault continued towards the south east The shock was felt in the ten southern counties of California and in a few places beyond, but serious damage to badly constructed houses was confined to an area of about 450 square miles, and was greatest in and near Compton and Long Beach No fault displacement was found at the surface The earthquake was followed by many after-shocks, some thousands being recorded by seismographs, but none of them comparable in strength with the principal shock, though a few increased the damage in buildings already injured

Acoustic Absorption In two recent papers (*Rend R. Ist Lombardo Sci Let*, Parts 11–15, 1933), Dr D Faggiani discusses the question of acoustic absorption by porous materials Previous theories which have been propounded lead to consequences which are not in agreement with the phenomena observed The new theory advanced by Faggiani is based on a consideration of the conditions of resonance of the very small channels into which the porous absorbing strata may be regarded as subdivided, and on the hypothesis that, in such conditions, the coefficient of absorption has, within suitable limits, a single value Application of these conceptions to the ideal case of a number of parallel channels of uniform radius and length leads to two conclusions which are in accord with certain of the empirical laws. Actually, in absorbent materials it may be assumed that the values for the lengths of the different channels are not constant, but are distributed about a certain most probable value When such variation is taken into account, there emerge further conclusions, all of which receive confirmation from the experimental data obtained by various observers with the most diverse porous materials.

Infra-Red Emission from Heated Metals. C. Hurst has recently published some observations on the emission of infra-red radiation by surfaces of copper and nickel (*Proc. Roy Soc.*, A, Nov.). The temperatures used were 700°–850° C for copper and 850° and 1,000° C for nickel, and the wave-length ranges lay between 1μ and 6 5μ. In the near infra-red region of the spectrum, the emissive properties change from 'optical' type to those characteristic of the electrical properties of the metal, and this change appears in the results of the present investigation The experimental method adopted was to compare the radiation from the metal surface with the black-body radiation from a wedge-shaped cavity in the metal The emitter was mounted in a vacuum chamber and heated by an internal tungsten spiral. The surface and the cavity were focused alternately on the slit of a rock-salt spectrometer, and the intensities compared by a thermopile and Paschen galvanometer A rotating sector cut down the black radiation to a convenient value for comparison The surface was prepared by grinding with emery paper and polishing with chamois leather, the metal was reduced with hydrogen to remove oxide films, and the values of the emissivity remained stable, in the case of copper, over weeks of work The experiments, taken in conjunction with the reflectivity measurements of Hagen and Rubens, made at room temperature, show that while the emissivity at short wave-lengths is not much affected by temperature, the emissivity at the longer wave lengths increases considerably with temperature as required by the classical electromagnetic theory The results have been compared with the theory of Kronig, who attempted to calculate with appropriate simplifying assumptions the motion of electrons in the periodic field of a metal lattice. The Kronig theory agrees less well with the experimental results in this region than does the classical theory of Drude, and the author shows that no simple modification of Kronig's theory is likely to explain the observed temperature variation of emissivity

Oscillations in an Ionised Gas It has been known for some time that oscillations may exist in a mass of ionised gas. R W Revans has recently described experiments in which stationary waves were set up in a bulb containing a hot cathode arc in mercury vapour (*Phys. Rev*, Nov. 15) In a 9 cm spherical bulb the strongest oscillation was just within the upper audible range, and a long train of harmonics could be detected The oscillations are apparently due to the vibrations of the glow as a whole comparably to those of the air in a Helmholtz resonator Over wide ranges of the arc current the frequency would remain constant and then at a certain value of the current the frequency would drop or increase suddenly due to a change to a different mode of vibration. The 'temperature' of the electron velocity distribution increases greatly when the glow begins to oscillate. A positively charged probe moved across the discharge showed maxima and minima in the collected electron current, indicating the presence of stationary waves The fundamental frequency agreed with that calculated from a formula of J. J. Thomson giving the velocity of waves travelling in an ionised gas The author intends to apply the idea of transmission of waves to the ionised atmospheres of stars, and in particular to disturbed areas such as sunspots.

Carbon Dioxide to prevent Ignition of Firedamp by Sparks. The Safety in Mines Research Board has just issued Paper No 81 on "The Prevention of Ignition of Firedamp by the Heat of Impact of Coal-Cutter Picks against Hard Rocks", written by Messrs M J Burgess and R V. Wheeler (H M S O , 6*d* net) It may be remembered that these same authors showed that firedamp could be ignited by the impact of coal-cutter picks against highly siliceous rocks They now point out that it is possible to prevent such ignition by discharging carbon dioxide into the cut made by the coal-cutter jib They arranged a flow of carbon dioxide by means of the solid form 'Drikold', manufactured for the market by Imperial Chemical Industries, Ltd , and usually in cylindrical blocks, 25 lb in weight, used in a standard liquifier, from which the gas could be delivered at known rates Their experiments are not very convincing, but their conclusions are that the possible ignition of firedamp when a coal-cutter pick strikes against a hard rock can be prevented by discharging carbon dioxide at the rate of at least 1¼ cub ft per minute into the cut Imperial Chemical Industries, Ltd , state that a continuous discharge of 1¼ cub. ft of carbon dioxide per minute would be obtained from 75 lb of Drikold, costing about 15*s* 6*d* As in 34 tests there were only 22 ignitions without the use of carbon dioxide at all, it is doubtful whether the coal mining industry will pay the price for a probable insurance against a possible accident, but the fact that a fair proportion of carbon dioxide prevents any ignition is decidedly interesting

The Gas Pressure Cable Recent progress in electrical engineering has been in the direction of ever-increasing voltages, but until quite recently this has not been accompanied by any radical change in cable design Up to 66 kilovolts, cables with solid insulating materials have proved satisfactory, but beyond this pressure new methods have to be devised In the *Electrical Power Engineer* of November–December 1933 an interesting lecture on this subject by Dr E. Bowden and F. W Main, given to the London Section of the Electrical Power Engineers' Association, is given in full The principle of the method used in the 'pressure cable' is to apply mechanical pressure radially to the insulation so that the vacuous spaces which tend to form in the material are either closed up or the pressure in them is raised to such an extent that no ionisation occurs The main difficulty to be overcome was to separate the pressure medium from the dielectric by an impermeable membrane. This was done by means of a thin lead sheath The gaseous pressure was applied from the outside, being confined in a pipe line The effect of this pressure produced a very marked improvement in the ionisation curve of the cable It was found that with nitrogen gas as the compressing medium, a pressure of eight atmospheres was sufficient to maintain the cable in a stable state. The first installation of pressure cable at 66 kilovolts on a commercial scale was completed about a year ago between Hackney and Walthamstow, the length of the line being about 2¼ miles The route went through a thickly populated suburban district and the pipes had to be threaded through gas and water mains, sewers, etc. The pipe is filled with nitrogen and a working pressure of 12 atmospheres is maintained The current carrying capacity of this type of cable is about 30 per cent higher than that of the usual type and its cost is about 25 per cent lower.

International Mathematical Congress Medals

EVERY four years there is held an international gathering of mathematicians, known as the International Congress of Mathematicians. At the next meeting, to be held in Oslo in 1936, two gold medals will be awarded to mathematicians selected for their outstanding contributions to mathematics by an international committee appointed for the purpose The foundation of these medals is due to the efforts of the late Dr J C Fields, research professor of mathematics at the University of Toronto Dr Fields was responsible for assembling the Mathematical Congress in Toronto in 1924—the only meeting which has been held outside Europe—and was president of the Congress and the editor of its *Proceedings*, which constituted two large volumes, published by the University of Toronto Press With funds remaining after the completion of the work, Dr Fields suggested the foundation of these medals, as a Canadian contribution to the cause of international scientific co operation, which he always had much at heart Unfortunately, Dr Fields did not live to see the realisation of his scheme, as he died in August 1932, a month before the meeting of the Congress in Zurich, which gave international approval to the foundation of the medals The medals will be awarded at each International Congress of Mathematicians in future

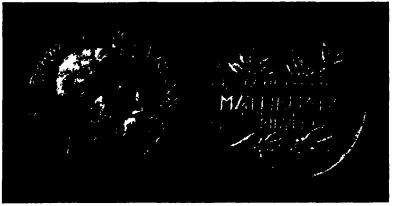

FIG 1 Medal of the International Mathematical Congress

In spite of the fact that the medals are of Canadian origin and are due to the personal efforts of Dr Fields, it was his particular wish that in design and award they should be truly international in character, and should not be associated with any country or person The task of designing a suitable medal was entrusted to the distinguished Canadian sculptor, Dr. R Tait McKenzie, R C A, who has now completed his work (Fig 1)

The medal is two and a half inches in diameter. The obverse shows the head of Archimedes facing right As there are no authentic portraits of this perhaps greatest of all mathematicians, recourse was had to the fine collection of more than thirty pictures collected by Prof. David Eugene Smith, and placed by him in Columbia University They show the idea of as many artists, ancient and modern, of what Archimedes may have appeared to be They naturally vary greatly, so the sculptor followed his own impression from reading his life and works He shows the sage as a man of mature age, vigorous, with curly hair and beard, straight Greek nose and prominent brow In the field is the word "Archimedous" in Greek capitals, and the artist's monogram, "RTM" and "MCMXXXIII"

The inscription surrounding it is: "Transire suum pectus mundoque potiri", which may be freely translated "To transcend one's human limitations and master the universe" This appropriate quotation from the Roman poet Manilius was supplied by Prof Norwood of the University of Toronto

The reverse has a label bearing the inscription. "Congregati ex toto orbe mathematici ob scripta insignia tribuere", which may be freely translated. "Mathematicians gathered together from the whole world honour noteworthy contributions to knowledge"

Behind the label is a laurel branch, and cut in the background can be made out the diagram of a sphere contained in a cylinder The determination of the relation of these two was one of the outstanding achievements of Archimedes, and this diagram was engraved on his tomb The name of the recipient will be cut on the edge of the medal and will not interfere with the design

Narcosis and Mental Function

IN a paper read before Section J (Psychology) of the British Association at Leicester, Dr J H Quastel, director of the Research Laboratory, Cardiff City Mental Hospital, gave an account of recent experiments with narcotics The evidence points to narcotics acting primarily by producing a state equivalent to anoxæmia at the particular parts of the nervous system where they are absorbed Also the psychological effects of narcosis and of oxygen want are very similar to each other.

The narcotic drugs tested have the common property of inhibiting, at low concentrations, the oxidation in the nervous system of substances important in carbohydrate metabolism, such as glucose and lactic acid, for which the effects are practically specific. If certain other substances are investigated which are freely oxidised by the brain, this inhibition of oxidation does not take place. The main effect of the narcotic appears to be at the nervous cells, where it interferes with the activation of the lactic acid molecule, a process which is necessary before its oxidation can take place. The narcotic and the lactic acid compete for the cell catalysts involved in the activation process

The following picture may be given of the mechanism of narcosis. Absorption of the narcotic takes place from the blood stream at a nervous centre There it competes with lactic acid for the cell catalysts, hindering the access of lactic acid to these catalysts and lowering the effective concentration of lactic acid available for oxidation. Hence the supply of energy is diminished; this produces a decrease in functional activity of the nervous centres in question and narcosis may ensue. It is clear from experiments—although much has yet to be done—that any mechanism resulting in deficient carbohydrate or lactic acid oxidation in the nervous system may well play a part in causing disorders of the functional activity of the nervous system.

The interesting question of the possibility of certain psychotic disorders having their origin in a state equivalent to oxygen deficiency at certain parts of the nervous system is thus raised. Evidence in favour of this possibility would be forthcoming if it could be shown that the body itself can produce substances which behave in a manner similar to narcotics This seems to have been accomplished by Quastel and other investigators at Cardiff. They have found that certain substances, mainly breakdown products of tyrosine and tryptophane, have precisely similar effects to those of the narcotics on the oxidation of glucose or of lactic acid in the brain at equivalent concentrations. Mescaline has a similar effect Most of the substances in question—tyramine, indole, and so on—are normally detoxicated in the body (chiefly in the liver), so that not more than traces can normally circulate in a healthy individual

A disturbance in hepatic functions, however, makes it not difficult to visualise the presence in the blood of more than ordinary amounts of these toxic substances, and their circulation over a long period would create a condition in the nervous system the psychological effects of which would be expected to resemble those found in anoxæmia or light narcosis Experiment has yet to show such a disturbance in detoxicating processes among certain psychotic types and attention is being focused on this problem

Prolonged narcosis as a therapeutic method, which seems to be satisfactory in certain cases in that it brings about an improvement in the mental condition, has been used in recent years Many, however, have abandoned it because of the production of toxic symptoms from the administration of the drug, which necessitated the cessation of this method of treatment before recovery was assured. A modified treatment of giving the patient a dose of glucose and an injection of insulin at the same time as the administration of the drug has proved very successful Ketonuria and other serious complications cleared up and the narcosis treatment became practically safe

Constitution of the Alloys of Iron and Manganese

THE latest contribution to the really remarkable work on the alloys of iron which has been carried out now for many years at the National Physical Laboratory is a paper by Dr. M. L. V. Gayler on the manganese-iron alloys, which was read at the meeting of the Iron and Steel Institute in September

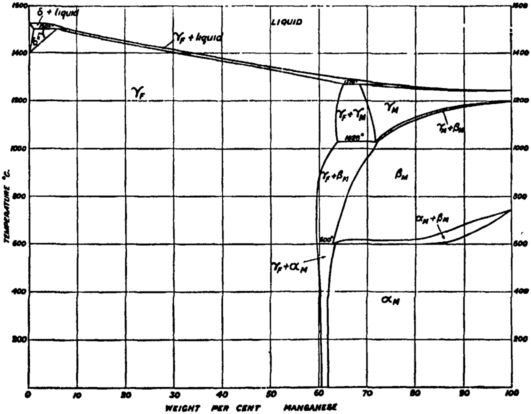

FIG. 1.

Fundamental work of this category demands as a preliminary the preparation of the elements themselves in a state of high purity. The iron employed was prepared electrolytically, treated in hydrogen at a temperature of 900°–1,000° C to remove oxygen, and then melted into ingot form in an induction furnace under hydrogen, being finally cooled *in vacuo* The manganese was distilled from the thermit product. The metals were then remelted in magnesia crucibles in an electric induction furnace, being allowed to solidify three times with intermediate remeltings prior to the final solidification To give an idea of the degree of purity of the final alloy the following composition of one with around 50 per cent of manganese may be cited carbon, 0 007, silicon, 0 023, sulphur, 0 014, phosphorus, 0 0013, manganese, 47 88 per cent

It is pointed out that the refractory materials available for the crucibles, thermo-couple sheaths, etc, has a profound effect upon the results in such work, and the analysis given above shows the extent to which the absorption of impurities by the metals from the refractories with which they have been in contact has been overcome To all workers with metals at very high temperatures the observations made upon the refactory materials which were tried will be of the greatest value The remainder of the experimental technique attains that high standard for which the work at the National Physical Laboratory in this field is famed

The diagram proposed is shown in Fig 1, reproduced from Dr Gayler's paper by courtesy of the council of the Iron and Steel Institute, which does not, however, contain data concerning the constitution of the iron rich alloys in the solid state This part of the problem still requires further work It will be seen that the δ transformation, which occurs at 1,504° C, extends from 1 to 8 per cent of manganese, after which γ-iron separates directly from the melt until the manganese content attains about 74 per cent Between 65 and 74 per cent of manganese a peritectic reaction occurs between this γ-iron and the manganese-rich liquid at a temperature of 1,270° C. to form a phase containing about 68 per cent of manganese With higher manganese contents, the solid solution containing the γ manganese phase separates directly from the melt

At the manganese end of the diagram the changes in the solid state have been determined with great care At a temperature of 1,028° C with a manganese content of from 64 to 72 per cent, the γ-manganese phase separates into γ iron and a β-manganese solid solution At 600° C a further transformation of the β-manganese takes place with the formation of γ iron and the α-solution of the manganese between 59 and 63 per cent of that element F C T

University and Educational Intelligence

IN "The Art of Teaching by Radio", Bulletin No 4 of 1933, the United States Office of Education has published a report intended to serve as a manual for those who aspire to broadcast the seed of learning That their number in the United States is large may be inferred from the fact that specialists in education by radio are employed on the staff of the Office of Education. It is indeed the senior member of this specialist staff who is responsible for the report, which is based on a very elaborate investigation conducted with the help of some hundreds of transmitting stations, the Association of College and University Stations, the National Association of Broadcasters, and other representatives of radio and educational interests It expresses a consensus of opinion among experts as to the best technique for preparing, advertising and transmitting educational programmes and as to preparing the ground for their reception by providing supplementary aids for listeners. Appended to it is a bibliography comprising ninety-one items, about a third of which have a European (chiefly British) origin It is a convenient summary, well adapted to serve its purpose Special sections deal with music, the drama, debates and dialogues.

SCHOOL administrators and teachers in the United States are exhorted by the Commissioner of Education in the September issue of *School Life* to co-operate in President Roosevelt's great national recovery scheme, so as to make school work a fitting preparation for life in the new world This formidable task is aggravated by the fact that the N R A code prohibition of employment of children less than sixteen years of age in industry and commerce automatically increases the school population by about 100,000 A more serious difficulty than the finding of accommodation for these additional pupils is the organisation of curricula suitable to the requirements of pupils of types for which the schools have not been accustomed to provide, and especially of those who have already been employed in paid work and are now obliged to go back to school This acute need for programmes of schoolwork appropriate to the requirements of 'working class' adolescents comes at a time when retrenchment policies have eliminated many of the courses in music, home economics, vocational guidance and the arts and crafts, and provisions for exceptional children The problem is discussed in an article entitled "The Children's Code" by one of the specialists in the Office of Education

FROM the Universities Bureau of the British Empire we have received a copy of a report of its executive council for 1932–33 The list of members comprises the nineteen universities of the British Isles, eleven Canadian universities (including all the larger universities except those of British Columbia, Manitoba and Montreal), the three principal Australian and the four South African universities, those of New Zealand, Malta and Hong-Kong and nine of the Indian universities Among the services rendered by the Bureau are the production of the "Year-book of the Universities of the Empire", the secretarial work of the Committee of Vice-Chancellors and Principals, the administration of certain trusts, including the Carnegie Corporation grant for enabling selected members of staffs of overseas universities to visit Great Britain, and assistance to overseas universities in the selection of candidates for academic posts Last year, the Bureau made arrangements for a visit of eight German professors (of theology, chemistry, medicine, English, ship- and airship-building, physics and architecture) to British universities No conference of the home universities was held, but regional universities' conferences were held in Australia (at Sydney in August 1932), South Africa (Vice-Chancellors' Committee of South African Universities, at Johannesburg in July 1932 and at Cape Town in February and June 1933) and India (Inter-University Board, at Hyderabad in February 1933). The report contains lists of subjects discussed at these conferences and at the quarterly meetings of the home universities' Committee of Vice-Chancellors and Principals. Appended to the report are fully annotated accounts for the year.

Science News a Century Ago

Phenology

The study of plant geography initiated by Linnæus and carried on by Humboldt and others was well advanced in the early years of the eighteenth century, but the study of the influence of climate on the growth of plants in different parts of the world was of later date. On January 22, 1834, Mr John Hogg addressed a letter to the *Philosophical Magazine* "On the Influence of the Climate of Naples upon the Periods of Vegetation as compared with that of some other Places in Europe" (vol 4, 1834, p 274), with the view of making the importance of this subject of study better known in England Most of the observations quoted are extracted from an Italian work on Naples or from Gilbert White, but Hogg was one of the first authors to attempt actually to work out the average dates of germination, flowering, fruiting, etc, of a number of plants in different regions, and to interpret the results in terms of climate, so that he may be regarded as a pioneer of the science of phenology.

Foundation of Electrochemistry

On January 23, 1834, and at meetings in two subsequent weeks, Faraday read before the Royal Society his important Seventh Series of the "Experimental Researches in Electricity" It is particularly in this Series, the outcome of his experiments in the autumn of 1833, that he establishes the principles of definite electro-chemical action upon which the science of electro-chemistry is based The paper contains his statement of the law "that the chemical power of a current of electricity is in direct proportion to the absolute quantity of electricity which passes", and a tabulation of 'ions' evolved on electro-chemical decomposition and the equivalent proportions in which they are produced, or their 'electro-chemical equivalents'. He describes in it his new instrument, "the only actual measurer of voltaic electricity which we at present possess", the 'volta-electrometer' or voltameter, and he defines the new terms, 'electrode', 'electrolyte', 'anode', 'cathode', 'anion', 'cation', he coined on the advice of Whewell and others

Magazine of Botany and Gardening

The following is an extract from a review by John Lindley, which appeared in the *Gardener's Magazine* of January 1834 "In Berrow's 'Worcester Journal', I have been shown the following advertisement: 'Published on the 1st of every month, the Magazine of Botany and Gardening, British and Foreign. Edited by J. Rennie, Professor of Zoology, King's College, London, assisted by some of the most eminent botanists in Europe; sixteen quarto pages of *original matter*.'—From the ingenious manner in which this is worded, it must doubtless be imagined by the public, as it was by the person who called my attention to the paragraph, that this original matter is furnished to Mr. Professor Rennie by writers whose names include mine. But, as I am not ambitious of the honour of being considered one of this gentleman's contributors, I shall be very much obliged if you will be so good as to allow me to state, through the *Gardener's Magazine*, that no original matter whatever has been either supplied or promised to Mr Professor Rennie by me. He has availed himself of some passages in works written by me, as he also has of others in the works of several of the writers mentioned in the advertisement; and this is, I presume, what is meant by being assisted; but, if so, the public should understand it rightly."

Fires in London

In a report on the fires in London in 1833 given in the *Mechanics Magazine* for January 25, 1834, it was stated that there were fifteen stations where men were on duty both day and night, four other stations were engines were kept, and at Kings' Stairs, Rotherhithe, there was a fire float. Although the steam fire engines patented by Braithwaite and Ericsson in 1829–30 had worked gratuitously at several fires in London with great success, there was prejudice against their use All the engines belonging to the Fire-engine Establishment were hand-worked, and were of the type introduced a century before by Richard Newsham, who by his invention of his "*engines for quenching fires*" it was said had given "a nobler present to his country than if he had added provinces to Great Britain". In 1834 there was no means of signalling to the fire stations and the watchmen on the bridges were often the first to give the alarm from seeing a reflection in the sky A shilling was usually given to the person who was the first to report a fire to a station, and by an Act of Parliament there were rewards respectively of 30*s*, 20*s* and 10*s*. to the first, second and third engines arriving on the scene. The number of fires attended by the Fire-engine Establishment in the year was 458, while there were 59 *false alarms* and 75 alarms from fires in chimneys The number of deaths through fire was twelve The London Fire-engine Establishment was founded by ten of the principal insurance companies on January 1, 1833, the headquarters of this concern was in Watling Street and Mr Braidwood was the superintendent.

Airy and Groombridge's Star Catalogue

Between January 11 and February 13, 1834, Airy, then Plumian professor of astronomy at Cambridge, was in London recuperating after a sharp attack of scarlet fever. During that time he drew up the papers for the Smith's prizes, which were awarded to Philip Kelland, of Queens' College, and Thomas Rawson Birks, of Trinity College, and began to examine the papers relating to the Star Catalogue formed by Stephen Groombridge. "I believe," he says, in his autobiography, "that it was while in London that I agreed with Mr Baily on a Report condemnatory of H Taylor's edition, and sent the Report to the Admiralty." Star catalogues had already been produced by many professional astronomers, including Bradley, Lacaille, Piazzi, Lalande, Argelander and Bessel They all entailed enormous labour and Airy said of Groombridge's Catalogue that, considering the circumstances, "the work is one of the greatest which the long deferred leisure of a private individual has produced".

Groombridge, who was born at Goudhurst, Kent, on January 7, 1755, was first a linen draper and then a West India merchant in London At his house in Goudhurst he set up a small observatory, but removing to Blackheath in 1802, he acquired a fine transit circle by Troughton with which in 1806 he began his catalogue. In about ten years he had accumulated some 50,000 observations, and he was engaged in reducing them when in 1827 he was attacked by paralysis. On his partial recovery he applied to the Board of Longitude for assistance in preparing the catalogue for the press. It ultimately appeared in 1832, the year Groombridge died, but owing to errors was suppressed Its revision was due to Airy. Elected fellow of the Royal Society in 1812, Groombridge was one of the founders of the Royal Astronomical Society He died on March 30, 1832 and was buried at Goudhurst.

Societies and Academies

LONDON

Society of Public Analysts, December 6 C. H Cribb: A specific gravity apparatus. In order to avoid the necessity for a water-bath with thermostatic control, the bottle, which has a thermometer stopper, is provided with a glass bulb sufficiently heavy to sink in any ordinary fluid and having a diameter about twice that of the neck of the bottle With this addition, the adjustment of temperature can be made to within a tenth of a degree in the course of a few minutes. G F. Hall and W. M Keightley · The excretion of aloes. Applying their modification of the Schoutelen reaction, the authors have shown that it is possible in some cases to detect unhydrolysed aloin in the urine for periods up to 60 hours after the aloes have been taken The unhydrolysed material can be detected at a later period than the hydrolysed drug, since the Schoutelen test is more sensitive than the Borntrâger test (for the hydrolysed drug) H E Cox · Chemical examination of furs in relation to dermatitis (4) Chemical reactions of dyeing with *p*-phenylene diamine and *p*-amino phenol A quantitative study of the oxidation of *p*-phenylenediamine by hydrogen peroxide in the presence of fur shows that the principal pigment formed is an azine combined with the fur proteins Some Bandrowski's base is found on the surface of the fibres, and there exists in the solution in the dye-bath much free *p*-phenylenediamine unoxidised, together with some Bandrowski's base and traces of quinone and ammonia Similar data are given in respect of *p*-aminophenol, which forms an oxazine in an analogous manner. The occurrence and properties of intermediate oxidation products in relation to dermatitis are discussed John Golding Use of the air-damped balance for the determination of total solids in milk Very rapid determinations of milk solids can be made by evaporating about 1 gm. of the milk in an aluminium cap (which cools very rapidly) and weighing the residue on an air-damped prismatic reflecting balance (Oertling) The influence of the time of drying on the results is shown in a series of tables G G Rao and K M Pandalai · Rapid method of determining minute quantities of nitrites. An iodimetric method has been devised in which the iodine liberated by the interaction of nitrous acid and hydrogen iodide is titrated in the presence of carbon dioxide evolved within the liquid itself. This prevents oxidation of the nitric oxide, also formed in the reaction, and expels it from the system, thereby eliminating the action of the resulting nitrogen peroxide on the iodide

PARIS

Academy of Sciences, December 4 (*C.R*, 197, 1369–1472). Emile Borel · The determination of the probability of series of rainy days and fine weather at the Parc Saint-Maur Hadamard: Observations on a recent note of Sixto Rios Reply to a criticism by Sixto Rios of a result of Mandelbrojt Gabriel Bertrand and Mlle. M. Andreitcheva: The comparative proportions of zinc in green and etiolated leaves There is a relation between the amount of zinc present in leaves and the coloration by chlorophyll. There is 2–3 times as much zinc in external green leaves as in the internal yellow leaves Where the etiolation is artificial the difference is greater. Louis de Broglie. The density of energy in the theory of light René Thiry was elected *Correspondant* for the Section of Mechanics. E J. Gumbel The limiting distribution of the greatest value amongst the smallest Richard Obláth. The theory of cubic constructions H Auerbach The number of generators of a limited linear group. René Dugas The establishment of Schrödinger's equation Bonnier and Moynot. The possible consequences of the use, in internal combustion engines, of hydrocarbons with a high antidetonating value. The adoption of anti-knock has not the same effect in all engines. In an engine which is normally in detonation, as is the case for many aviation engines, the change of the fuel produces a rise in the temperature of the escaping gases In engines less pushed, with little or no detonation, the variation of the escaping gas temperature is less marked Jean Chazy. The uniform integrals of the problem of three bodies Jules Géhéniau The fundamental laws of the L de Broglie wave in the gravific of Th De Donder Pierre Vernotte. The absolute measurement of the coefficients of thermal conductivity of gases. The apparatus described avoids the complication due to convection Michel Anastasiades. The mechanism of rectification in copper sulphide–magnesium rectifiers According to the author's theory, cuprous sulphide is produced from the cupric sulphide, and the rectification is mainly due to the contact Mg/Cu_2S. E Thellier. The permanent magnetism of fired earths A brick earth, heated uniformly in a magnetic field, is uniformly magnetised, this magnetisation depending on the conditions of time, temperature and atmosphere of the furnace The magnetisation is permanent. J Genard. The magnetic extinction of the fluorescence of diatomic molecules of sulphur The action of the magnetic field on the fluorescence of sulphur vapour is complex Some lines are extinguished, others appear to be unaffected, whilst some are strongly enhanced E Rinck Solidification diagrams of alloys formed by two alkali metals. The sodium-rubidium alloys No evidence was obtained of the existence of the compound Na_2Rb corresponding to the compound Na_2K. Pierre Auger and G Monod-Herzen The presence of neutrons in cosmic radiation. Marcel Godchot, Etienne Canals and Mlle. Germaine Cauquil: The Raman spectrum of some substituted cyclenic hydrocarbons. Jean Cournot and Henri Fournier: Comparative results of the measurement of corrosion. Albert Saint-Maxen and Emile Dureuil. The absorption spectrum of the diphenols in alkaline medium. The results confirm the hypothesis of Euler and van Bolin, relating to the existence of a compound of quinone structure in alkaline solutions of hydroquinol. Augustin Boutaric, Maurice Piettre and Mlle. Madeleine Roy: The physicochemical study of the flocculation of myxoprotein by resorcinol. Picon · The titanium sulphides. A description of the preparation and isolation of three new sulphides, Ti_2S_3, Ti_3S_4 and Ti_4S_5 B. Bogitch: The preparation of ferrochrome in the electric furnace Description of experiments on the semi-industrial scale on the direct reduction of chromite by retort carbon. AUGUSTIN MACHE: Contribution to the study of hydraulic mortars. A MAILLARD: The hydrogenation of naphthalene. A study of the causes of the anomalies found in the hydrogenation of naphthalene in the presence of catalysts. In the gas phase, there are two successive reactions producing the tetra and hexa hydrogen addition compounds. The reaction $C_{10}H_8 + 5H_2 = C_{10}H_{18}$ has not been observed D LIBERMANN: The preparation of the salts of trioxytriarylsulphonium derivatives of the para and ortho substituted phenols and on the arylsulphonium bases PAUL CORDIER The condensation of benzylpyruvic acid with benzyl cyanide. An acid nitrile is formed by this condensation. the corresponding dicarboxylic acid is unstable, it loses water and is converted by an isomeric change into the anhydride of an ethylene dicarboxylic acid ANTOINE WILLEMART Isomeric transformations of the hydrocarbons $C_{42}H_{30}$, isomers of 1, 3, 1′, 3′ tetraphenyl-1, 1′-dihydrorubene GEORGES RICHARD: An oxido-reduction of 1-chloro-1, 2-diphenylethanal and on a supposed tolane oxide MARCEL TUOT. Some ethylene and saturated hydrocarbons containing eight and eleven atoms of carbon PAUL GAUBERT. Liquid crystals produced by the evaporation or cooling of an aqueous solution of tartrazine. ROBERT LAFFITTE: The tectonic of the south of the massif of Aurès. ALBERT DE LAPPARENT The synclinal of Rians (Var) J P ROTHÉ Morphological observations at Scoresby Sound. RAYMOND CIRY: The eastern termination of the primary Asturian massif and the structure of the Mesozoic region which envelopes it towards the east G DEDEBANT: The envelopes of isobars F. M. BERGOUNIOUX: Remarks on the fossil Chelonians of the family of Amphichelydæ. W C DARRAH and P. BERTRAND: Observations on the flora of the Pennsylvanian coal measures (regions of Wilkes-Barre and Pittsburgh) MLLE A MICHAUX. The calcium contents of striated muscle and liver in normal guinea pigs and guinea pigs suffering from starvation, acute scurvy or chronic scurvy. RENÉ HAZARD: Potassium, an element producing adrenaline The effects produced by the injection of solutions of potassium chloride resemble those produced by adrenaline N KOBOZIEFF. The diversity of the genotypical constitution on mice with a normal tail. ÉTIENNE WOLFF. The experimental production of otocephaly and the principal malformations of the face in the fowl. D. BACH and D DESBORDES. The direct transformation of nitrates into ammonia by the mycelium of the lower fungi A and R. SARTORY and J. MEYER: The evolutive cycle of the Actinomyces in cultures after passage through a collodion ultra-filter. J. LAIGRET: The reproduction of murine leprosy in the guinea pig and rabbit, treated with an acetone extract of tubercle bacilli. VICTOR PAUCHET, PIERRE ROSENTHAL and HENRI BERTREUX: The treatment of surgical shock by fresh embryonic juices.

GENEVA

Society of Physics and Natural History, October 19. E JOUKOWSKY and CHARREY: A levigator with immovable liquid medium. The authors have constructed an apparatus in which the precipitation takes place in a cylindrical tube. A sand can be separated into a very large number of sizes, up to complete precipitation, and a large number of points on the curve of precipitation can be determined. LÉON W. COLLET: The gneissic mylonites of the southern side of the Tour Sallières. The author describes four different outcrops of gneissic mylonites in the sedimentary substratum of the Morcles Nappe. Two of these lenticles are located on the thrust plane of the Nappe. The two others are situated at the base of slices of the autochtonous rock and are in relation with crystalline wedges of the Aiguilles Rouges massif STUDER: Geological sketch of the neighbourhood of Renéville, French Congo

ROME

Royal National Academy of the Lincei, June 18 A. BEMPORAD: Stellar currents about R.A. $13^{h} + 52^{\circ}$ Decl. E ALMANSI: Deformations of elastic strips (7) P. VINASSA DE REGNY Age of the white chalk of Mount Casale, near Palermo Fossil studies show that the Mount Casale deposits must be ascribed, not to the Lower Lias, but to the Trias. L. PETRI: Ionising action of fresh vegetable tissue pulp and mitogenetic radiations. In continuation of earlier work, it is found that, with potatoes, the emission of mitogenetic radiations ceases and oxidation processes are greatly enfeebled when the tubers are cooked, whereas in the live tubers oxidising enzymes are very active A. DEL CHIARO An inequality of Jensen I. OPATOWSKI: Biharmonic functions as products analogous to Lamé's products, and the lines of force of Newtonian fields (1) J. C. VIGNAUX: A theorem on the double integrals of Abel and Laplace G. KRALL: Motion of a planetary system of $(n + 1)$ rigid bodies; its stationary limiting aspects Proof is given of the statement made in an earlier communication. celestial bodies having the structure of a planetary system, subject to tides or any internal dissipative actions, tend to have their baricentres on a straight line revolving with uniform velocity round the common baricentre in a plane determined by the initial data. A. COLACEVICH: Excess of colour and the *K* calcium line in interstellar absorption NELLA MORTARA. The use of liquid air for the purification of radium emanation B. ROSSI: The disintegration of lead by the effect of penetrating radiation. G. A. BARBIERI: A new type of complex compounds of bivalent silver. The anhydrous salt, silver picolinate, $Ag(C_5H_4N\,CO_2)_2$, is described. A BARONI Mixed sulphonic anhydrides (1) Preparation of acetosulphonic anhydrides Mixed anhydrides of acetic acid with methane-, ethane-, benzene- and *p*-toluene-sulphonic acids have been obtained by the action of the chlorides of the sulphonic acids on silver and sodium acetate. The mechanism of the decomposition of these anhydrides seems to be of the same type as that of mixed anhydrides of ordinary organic acids F P. MAZZA and A CIMMINO Dehydrogenase activity of *Bacillus coli communis* on higher fatty acids. Palmitic, oleic and, especially, stearic acid are dehydrogenated by this organism. The velocity of the action diminishes in the fatty acid series with increase of the molecular weight up to the C_8 or C_9 member and afterwards increases continuously. G. PICCARDI: Detection of europium, and three lines of extreme sensitivity. The flame spectra of certain mixtures of rare earth oxides revealed three intense europium lines of wave-lengths 4461, 4627 and 4594, which at low temperatures are highly sensitive. A. CHIARUGI: Development of the female gametophyte of *Weddellina squamulosa*, Tul (Podostemonaceæ). PAOLA PARDI: Contribution to the cariology of the Asclepiadaceæ B. DE LERMA: The pharyngeal bodies of the Orthoptera, proof of the existence of endocrine glands in arthropods.

The Chemist in Industry

DR. H. LEVINSTEIN, a past president of the Society of Chemical Industry, recently delivered before the Institute of Chemistry a discourse entitled "The Chemist as a Directing Force in Industry". While emphasising that there are other branches of special knowledge besides chemistry which are necessary to business, Dr. Levinstein declared that there can be no better training for industry in general—not alone for the chemical industry—than a sound training in science Too few in Great Britain have had such a training, too few of our business men, our politicians and our very able civil servants Yet mere knowledge or talent is not enough, "it is the man that matters" It is not necessary to be a chemist to control even a dyestuff manufacturing business, it is merely a great advantage to be one Chemists must not be regarded as one class, or as a class apart Chemical training is varied, but it cannot be more than an excellent preparation, what can eventually be accomplished depends on the individual or upon the opportunities which he can find or make

An increasing number of people who have had such training is being employed in administration in the big chemical and other industries, but there is no indication that politicians, financiers and bankers are making the slightest progress in this direction Finance houses and banks might well employ, as a routine procedure, men thoroughly trained in chemical industry. In Great Britain we have too little 'educated money', too little realisation of the value and applicability of the technologist's training and methods Inventions are too often regarded as accidental, whereas they are in truth created by researches directed to a specific purpose by trained minds Moreover, it is sometimes forgotten that the amount of a substance produced is not an accident, but is determined by the demands of trade, by the capital available, by the profits to be made, and often by the supply of raw material

As an example of the serious results of neglect of such considerations by those in authority, Dr. Levinstein quoted the payment of gold to the United States of America on account of war debts. Like every other industry, the gold mines of South Africa regulate their production of gold according to the demand which they can profitably supply. The cost of raising capital, economical and prudent working, and the world's requirements for their products are naturally their principal considerations The gold which we agreed to pay America—some 220 metric tons annually—is taken from stock. No effort is made to manufacture the extra quantity required from the raw material available in plenty, to earmark any portion of the new production of gold for debt payment, or to limit in any way the use of gold for unnecessary purposes In every particular we fail to take the elementary precautions which a trained technologist would have taken, had he been called upon to advise What should we think in business of a sales department which made contracts to deliver without consulting the manufacturing side or even the research department, which neglected to do every one of those things that are elementary in any properly conducted business ? During the years that currencies were being debauched in order to ship gold to America, India was taking almost as much gold as America, because our policy made it attractive Since Great Britain went off the gold standard, most of the gold which we shipped to India has come back, but after causing misery and poverty, undeserved and unnecessary, in every social class in half the world

Speaking of the relations between industry and the State, Dr. Levinstein referred to changes wrought by the War in many countries, and said that industrial history is being made very rapidly All political or social changes in one nation react remarkably quickly on all others Apart from the spread of new social theories, there is the fact that if the industries of one or two important States can act as a unit, a similar concentration or simplification in some form or other will be forced upon us. We already have compulsory quota and compulsory marketing methods, and trade agreements with other countries are likely to lead to novel restrictions on the construction of new plants Whereas up to now any person making an invention has been free to erect a plant to carry out his invention, it may in future be necessary for inventors or enterprising individuals who wish to be their own masters to obtain a permit before they can be allowed to build

The latter part of Dr Levinstein's discourse was devoted to an examination of the close relations between science and industry in Japan, and had special reference to the dependence of the pearl industry on scientific investigation and application Until a few years ago, the pearl industry of the East was as big a gamble as that of gold-mining before the introduction of the Forrest-MacArthur cyanide process, the pearl oyster was scarce, and the yield of good pearls was entirely a matter of chance. Now the breeding of oysters for pearls in Japan has become an industry analogous to the breeding of silk worms, the cultivation of the pearl oyster is recognised in Japan as a matter of national importance, and—this with reference to Mr Mikimoto, by whom the industry has been methodically built up—people who do things of national importance industrially in Japan are encouraged and honoured by those in high places The production of culture pearls, a delicate and lengthy operation described by Dr. Levinstein, is, as he said, truly a romance of science and industry in a novel form

Another great technical achievement is the development of the Japanese artificial silk industry. In fact, every industry which one looks at in Japan shows the same highly skilled planning, both on the technical and on the commercial sides Important technical results accrue from the work of the Institute of Physical and Chemical Research, which was founded in 1917, and has a trained research staff of four hundred Japanese industry is to-day armed with every weapon of the modern industrial armoury, and its competition is of importance to British chemical industry not only because Japan is a diminishing customer for chemicals, but also because the outlet for our inventions is half choked if the flow of orders from the great bleach works, dye-houses, and calico-printing works of Lancashire and Yorkshire is checked The intimate connexion between industry and the State is apparent; lost orders rapidly become matters of political importance. The problems involved call for the man of knowledge and action, and we agree with Dr. Levinstein that training in science, particularly if followed by works practice, gives that unique experience which aids in every type of constructive work

Everyman's Guide to the Plant Viruses

Recent Advances in the Study of Plant Viruses. By Dr Kenneth M. Smith Pp. xii+423. (London . J and A Churchill, 1933) 15*s*.

DR KENNETH SMITH is to be congratulated heartily on producing a succinct, clear, readable and excellently illustrated account of the present state of knowledge concerning the plant viruses In view of his many other activities the achievement is a remarkable one. The book will be of the greatest service not only to virus workers, but even more so to those in the related fields of botany, bacteriology and agriculture, to whom, for the first time, it presents a coherent account of the subject free from the minutiæ of technical papers

Beginning with an introductory chapter, the author passes to a consideration of symptomatology, which is a difficult and debatable subject, and then proceeds to a good account of pathological histology, including a useful comparison with animal virus diseases Two chapters are devoted to an excellent treatment of the physical properties of viruses, including practical directions for the preparation and use of graded collodion ultrafilters following Elford's method.

The next three chapters deal with insects in relation to viruses, and they are, as would be expected, excellent It is interesting to note that only three of the twenty-three orders of insects are implicated in the spread of plant viruses, and that the sub-order Homoptera contains about 90 per cent of all known vectors The evidence is presented *pro* and *con* on the unsettled question of the relationship between virus and insect, whether an obligate one and therefore leading to the presumption of a development cycle of the virus within its vector, or a casual physico-mechanical relationship The latter would appear to be favoured by the gradually accumulating evidence, notably the author's transmission of spotted wilt by means of *Thrips tabaci* in England, while it is associated with *Frankinella insularis* in Australia (which parallels the more doubtful case of curly top of sugar beet), the recently accomplished needle-transmission of the latter virus, and generally the discovery of multiple vectors for so many diseases, such as leaf-roll Further advances are likely to follow from Storey's delicate gut-puncturing operation on leaf-hoppers, whereby the virus gains access to the body fluids, as a result of which hoppers previously 'inactive' become vectors of streak.

Four chapters are devoted to the transmission of virus diseases by other means, to the physiology of diseased plants (a good account largely following Henderson Smith) and to general aspects of virus diseases, such as carriers, recovery, immunity, variations in virulence, virus adaptation, composite virus diseases and the separation of virus mixtures, all of which are succinctly and excellently treated

The last three chapters are made up of short descriptive lists, which are not exhaustive, of the virus diseases of plants. This is one of the least satisfactory parts of the book. Few will accept the author's grouping of the potato virus diseases, and it is remarkable that in the case of this crop alone does he confuse a virus with a virosis—a useful word which is rejected An attitude more detached and judicial would have led to a better treatment Those who are familiar with the author's papers will have some difficulty in recognising his best-known theories in their present form, but it is impossible to discuss this matter here. In any future edition it would be well to treat of crop losses and economic applications much more fully.

Taking the book as a whole, the outstanding features are the co-ordination of work on the animal and plant viruses, which workers in both fields will find stimulating, and the excellent bibliographies, brought down actually to the middle of 1933, for which alone the book would be worth its price These are appended to most chapters, and are not merely lists of titles, but are discussed so far as space permits One or two notable omissions may be referred to, such as the original discovery of the insect transmission of leaf-roll by Oortwijn Botjes in 1920, that of potato carriers by Atanasoff in 1925, and the finding of the *A*-chlorosis and *B*-chlorosis of the Malvaceæ by Hertzsch in 1927, whereby he reconciled the work of Lindemuth and Baur The book closes with an author and subject index, except for 16 pages of disfiguring publisher's announcements at the end

In a discipline so young, it may be asked which are the recent advances and which the older ? It will surprise most people to learn that potato mosaic was first seen by Orton, an American, in a German field in 1911, the irony of this being that not a single commercial American potato plant has since been found which is free from mosaic To this author's classical bulletin of 1914 we owe the specific name leaf-roll (philologically preferable to 'leaf roll') and the first mention of potato mosaic and streak With whom shall we begin the modern period ? With Orton, or Appel who inspired him, or Allard who conveyed the classical tobacco mosaic to potato in 1912, or Quanjer who discovered the infectious nature of leaf-roll in 1916 ? None of these papers is mentioned. The reviewer would say that the 'recent' period begins with Quanjer's paper of 1916, and he would like a student approaching the subject to do so in a filial and historical spirit, contrasting the trackless jungle of degeneration theories, from Parmentier downwards, which existed before

1916, with the path which was then so magically opened through it Or if 1916 is too remote, then he would say that the modern period begins with the general adoption about 1923 of the Wageningen greenhouse equipment and methods, which every country has copied, for all results of value have flowed from them

A striking feature of the bibliography is the immense preponderance of work in the English language Even if one were to admit that some of the other languages have not been gleaned so thoroughly, yet it is true that practically all the creative work (work in Dutch excluded) has appeared in English, and to this all the English-speaking countries have made first-class contributions, including besides Great Britain, Ireland and the United States, Australia, Africa, India and Canada

Virus workers—how long must we wait for 'virologists' [2]—have a gratifying esoteric feeling of working in a new medium in which anything may happen because it transcends the ordinary laws For this reason they have not been popular with their fellows, who have failed to understand what they are doing, if anything, except squabbling incomprehensively The present book removes this reproach, and virus workers themselves may, looking back over the labours of the last seventeen years, congratulate themselves *se valde profecisse* They have compiled a body of learning which fits the facts of Nature, explaining what was previously inexplicable, and their theories are still fruitful There is no other criterion of the truth PAUL A MURPHY

The Intimate Structure of Fibres

Fundamentals of Fibre Structure By W T Astbury Pp x + 187 (London Oxford University Press, 1933) 8s 6d. net

IT is a not uncommon complaint that the trend of thought in modern physics has been in such a direction as to make it almost impossible to devise an extended course of lectures suitable for extra-mural students The study of quantum theory, wave mechanics, potential barriers and the like demands a mathematical equipment and a technical knowledge quite beyond the compass of those whose training, in mathematics especially, has not been regular and systematic

That there is something in the complaint is seen in the practical fact that physical subjects do not bulk largely in adult educational syllabuses. Here and there, swimming rare in the vast whirlpool of courses on economics, music, and all possible cultural aspects of literature, may be found a lonely set of lectures on the history of the physical sciences or on some astronomical topic; but on the whole, physical subjects are poorly represented in such syllabuses—a very different state of affairs from that which held fifty or sixty years ago when, to hear Tyndall, crowds queued up at the Free Trade Hall as at a theatre The fault may be in the subject, or may be in the teacher

Mr Astbury's admirable lectures seem to show that, given an enthusiastic and clear-headed teacher, who speaks of what he really knows from first-hand acquaintance with the subject, an elucidation of some of the most recondite problems of modern physics may be satisfactorily presented to a lay audience

X-ray analysis, of course, lends itself specially to exposition by means of models—using that word in a very wide sense—and Mr Astbury has not been slow to avail himself of such assistance as models can afford He has not been afraid to begin at the beginning, and by means of happy analogy and illustration has built up an atomic and molecular world in which his hearers, almost without realising the complexities with which they have to deal, are led from a molecule of hydrogen to those of methane and of benzene and, in a very little time, are finding structures such as that of tri-olein no more difficult to handle than that of ethyl alcohol

The story of the X-ray analysis which has unfolded the crystalline structure of fibres is one of the most fascinating of the tales that applied science has to tell, and the story loses none of its fascination in the skilled hands of Mr Astbury It is clearly and authoritatively told by one who has played a large part in its development. The titles of his successive lectures—the fundamental nature of matter and radiation , the invisible fibres of the world of molecules , how atoms and molecules make patterns in space ; an X-ray view of the inside of a textile fibre , the fundamental structural difference between wool and other fibres ; and some inside information about the properties of the wool fibre—show sufficiently well the lines along which Mr Astbury has developed his thesis

The textile students of Cleckheaton are to be congratulated on their privilege of hearing these lectures which, in their present form, should appeal to a very wide audience.

ALLAN FERGUSON.

Compression-Ignition Engines

High Speed Diesel Engines, with Special Reference to Automobile and Aircraft Types an Elementary Textbook for Engineers, Students and Operators By Arthur W. Judge Pp viii+248+35 plates (London Chapman and Hall, Ltd, 1933) 10*s* 6*d* net

MR JUDGE set himself a difficult task when he decided to compress into less than 250 pages an account of high-speed Diesel engines, which (as he hopes in the preface) will be equally suitable for engineers, students and operators The needs of the second and third of these groups, if not almost mutually exclusive, are at least difficult to harmonise the operator must think chiefly of details whilst the student's essential need is to grasp general principles and view the subject as an articulated whole Nonetheless, the author has achieved his aim in a remarkable degree, and no one who professes, or desires to profess, a close acquaintanceship with this type of engine can afford to ignore Mr Judge's contribution The title chosen for the book may be questioned, though the author makes some defence of his choice in urging that the name Diesel engine is more readily recognisable than compression-ignition engine There we think he is wrong, the latter name is already well enough known to those for whom he writes even if not to the world of the "Press and General Public" to suit which his choice of title was, he admits, mainly selected

One of the chief uses of this engine is found in road transport In the sixteen different makes on the road there are very varying standards of performance, but it is understood that more than one hundred motor vehicles using one of these engines are now on the road in London alone, and any criticism of their performance arises not because of failure in thermodynamic efficiency but mainly because, owing to the youthfulness of design, maintenance troubles loom rather large.

Another important field is that of aviation Here the great potential gains are the lessening of fire risk on crash, and the elimination of radio interference from ignition gear Both of these are of first-rate importance and the former can scarcely be over-emphasised, especially for civil air transport

On p. 196, the author gives an illustration of the rather complex Jumo engine which is a triumph of the illustrator's art · the credit for this he gives to our contemporary, the *Mechanical World* The illustrating work throughout is of a high level, and we think the author is to be congratulated upon the care he has taken to attain a high level in this regard Furthermore, his book gives the best short account we have seen of the various cylinder combustion-heads which have been tried, and of the important aim and purpose which lies behind them We have no hesitation in recommending this book as a valuable addition to any engineer's library

Problems in Mental Deficiency

Stoke Park Monographs on Mental Deficiency and other Problems of the Human Brain and Mind No 1 *The Burden Memorial Volume* Dedicated to the Memory of the late Rev Harold Nelson Burden Edited on behalf of the Medical and Consultant Staff of Stoke Park Colony, Stapleton, Bristol, by Dr Richard J A Berry Pp xix+249+29 plates (London Macmillan and Co, Ltd, 1933) 10*s* 6*d* net

IN this volume there is collected together a series of papers, dealing with the problems of mental deficiency, by a variety of authors, most of whom are members of the medical staff of Stoke Park Colony Two thirds of the articles have been previously published though they appear in this collection in slightly modified form

The first paper, which is the longest in the series, concerns the detection of potential 'social inefficiency' by physical and mental measurements, and was originally published in 1920 It contains a comprehensive table giving norms of the brain capacity of Australian children, calculated by one of Lee's formulæ The writer of the article, Prof R J A Berry, holds that there is a fairly constant relationship between head volume and intelligence, and he applies this hypothesis to the diagnosis of mental subnormality. He attributes the relatively small size of the heads of some delinquent and defective children to the incomplete development of the cerebral cortex The proportion of mentally subnormal individuals who have head measurements which do not deviate significantly from the normal is not indicated and without this knowledge it is difficult to see how cranial capacity can be of much diagnostic importance in a given case. The diagram shown on p. 26, apparently showing the relationship between mental age and cranial capacity, is misleading The correlation between these two variates is weak and many mental defectives of imbecile and idiot grades have heads of normal dimensions

One of the new papers gives a detailed analysis of cellular changes found in the brains of three defectives It is concluded that the more severe the grade of defect, the more disorganised is the histological picture of the cerebral cortex Another original article, by R M Norman, seeks to demonstrate a relationship between these cellular deficiencies in the cortex and neurological abnormalities which are to be found among mentally defective patients

In a short paper, published for the first time, R. M Bates describes three rare developmental abnormalities which have been found in association with mental retardation. This article is particularly good and it is well illustrated. It records a case of anomalous cervical vertebræ, a case of bilateral facial palsy with club-feet and an example of what is clearly acrocephalosyndactyly

Though there are many statements in this book concerning which research workers in mental deficiency and related problems will disagree, they will find it convenient to have the essays collected in a single and well-printed volume

Short Reviews

Edwardian England A D 1901–1910 a Series of Lectures delivered at King's College, University of London, during the Session 1932–3 Edited by Prof F. J C Hearnshaw. Pp 285 (London Ernest Benn, Ltd , 1933) 10*s* 6*d* net.

THIS book contains the latest of the well-known series of public lectures arranged by the History Department of King's College, London. "Edwardian England" may be said to include the first decade of the century, but there would be only a verbal incorrectness in extending it to the outbreak of the War. Edward VII's two main interests were society and foreign policy With regard to these two aspects of public life in England, there really was an Edwardian period But the same remark can scarcely be made of, for example, literature and science

Still, as Prof. H. Levy shows, in his illuminating lecture on the advance of science during the period, any link in the chain may be isolated for special study He rightly insists that it was appropriate in this lecture to regard science, not merely in an abstract sense, but also as permeating the social life of the time. It was the Edwardian period, for example, which saw the transition from dimly to brilliantly lighted streets and buildings, with consequent changes, on a great scale, in the uses of leisure. Passing from the effects of applied science upon social practice, Prof Levy refers at some length to the experimental and theoretical investigations that were maturing during the period. Here, what he has to say about relativity seems to us as clear as any popular explanation that we have encountered Naturally Prof. Levy's references to biology are briefer, but he explains how during the Edwardian period evolutionary theory advanced from a qualitative to a quantitative and measurable stage Both in scope and in treatment the lecture is a fitting contribution to the volume in which it now appears.

Annals of the Royal Botanic Garden, Calcutta. Vol 13 · *Asiatic Palms—Corypheæ.* Posthumous Work by Dr Odoardo Beccari Revised and edited by Prof Ugolino Martelli Pp vii+356. 50 rupees, 75*s*. Plates Pp v+102 plates. 26 8 rupees, 40*s* 6*d* (Calcutta Bengal Secretariat Book Depot, 1931)

FEW groups of plants are more difficult to comprehend systematically than the palms, and this is mainly due to the bulkiness of adequate specimens causing them to be largely neglected by explorers, so that we welcome the continuation of this great work on Asiatic palms by the late Prof. O Beccari, published posthumously by Prof. U. Martelli No eastern botanist ever possessed the knowledge of Asiatic palms which Beccari in his travels in Malaya, one of the richest palm areas in the world, had accumulated The Corypheæ are especially interesting as they appear to be the oldest known group occurring in the Eocene, and almost the only palms found in temperate regions, the unique European palm *Chamærops* being one of them

Besides full descriptions of the Asiatic species, illustrated by photographs of specimens, the author has added a very useful list with localities and diagnoses of those of the New World, with anatomical drawings of flowers and fruits All that now remains of Beccari's manuscripts in the capable hands of Prof. Martelli and awaiting publication, are those dealing with the Arecineæ, for the Lepidocaryinæ and Borassineæ were published in the Calcutta *Annals* before Beccari's death and the Phœnicineæ (dates) in Malesia. With the publication of the remaining portion the whole work will stand for ever as a worthy monument to one of Italy's greatest botanists, and this we hope will be carried out by Prof Martelli, who is much to be congratulated on the work of revision and publication of the present volume.

H. N. R.

Marie Stopes: her Work and Play. By Aylmer Maude. Authorised edition. Pp 299+8 plates. (London: Peter Davies, Ltd, 1933) 8s. 6d. net.

DR. MARIE STOPES is a remarkable woman; and if she were unaware of the significance of her work and influence, Mr. Aylmer Maude's book could not fail to enlighten her. It is not given to many workers in the realm of science—natural or social—to have their biographies published during their lifetime; so that Dr. Marie Stopes is fortunate in this respect and also in her biographer, whose literary gifts enable him to present a pleasing portrait of his subject

Dr. Stopes's scientific work in palæobotany, the composition and structure of coal, and related subjects, belongs to the first rank and has both scientific interest and practical value The general public knows nothing of her eminence in these fields and associates her name only with the subjects of birth control and problems of sex. For the enlightened view now taken of these matters by most people, the chief thanks are due to Dr. Stopes, whose work marks a new epoch in the life of the community Mr Maude is evidently an ardent disciple of this pioneer of social hygiene and intelligent reproduction of the human species; and on this account we ought perhaps to overlook the exalted position in which he sometimes places her Several of the chapters might have been abridged with advantage, but on the whole the book is a faithful record of Dr Stopes's activities in many directions

Elements of Optical Mineralogy. an Introduction to Microscopic Petrography By Prof Alexander N Winchell Third edition. Part 2 *Descriptions of Minerals, with Special Reference to their Optic and Microscopic Characters.* Pp xviii+459 (New York· John Wiley and Sons, Inc.; London. Chapman and Hall, Ltd, 1933.) 37s 6d net.

THE general arrangement of the third edition of Pt 2 of Winchell's "Elements" remains broadly the same as in earlier editions. Advances in knowledge of the relations between the optical properties and chemical composition of crystals, especially those affecting the amphibole group, have been incorporated in the text.

An important change has, however, been made in the chapter on the silicates, which occupies more than half of the book. This large group of minerals has been re-classified, so far as is at present possible, on the basis of the results obtained in recent years from X-ray crystal analysis. This change-over, with its subordination of chemical composition to crystal structure, is of the greatest theoretical interest In effect it summarises the results of all the work done on the silicates in recent years.

This is an invaluable work for students and research workers in mineralogy and petrography, It is therefore unfortunate that the slight increase in size of the latest edition should be accompanied by so very considerable an increase in price.

The Official Year-Book of the Scientific and Learned Societies of Great Britain and Ireland· with a Record of Publications issued during Session 1932–1933. Compiled from Official Sources. Fiftieth Annual Issue Pp. viii+171. (London: Charles Griffin and Co, Ltd., 1933) 10s net

THE publishers of this Year-Book are to be congratulated on their enterprise, for the present year marks the jubilee of its issue There can be no question that the existence of such an annual volume has promoted the interests of science generally and of the societies with which it deals, by providing accurate details of the numerous scientific bodies in the British Isles The present issue is on the usual lines, the various societies are classified into 14 groups The officers, membership, dates of meetings, and publications of each society, institute, etc, are given, and in many cases further details, such as the objects of the society, are appended A good index, and a logical grouping of the societies make it quite easy to refer to any society. All information incorporated in the volume is compiled from official sources, it is, indeed, a work of ready reference, worthy of support by scientific societies.

Modern Theories of Development· an Introduction to Theoretical Biology By Ludwig von Bertalanffy Translated and adapted by J. H. Woodger Pp x+204 (London: Oxford University Press, 1933) 8s 6d net

THIS important introduction to theoretical embryology is well-known to all those interested in the subject The English translation and adaptation by Dr Woodger will make it available to a wider circle of readers. The author proposes as a solution to the crisis of present-day biology, the constitution of a purified science which would relate and explain the accumulated facts pertaining to the study of living organisms As a synthetic principle of this science, the author proposes an organismic theory which would aim at the establishment of the laws of biological systems based on experimental data and on the possible use of mathematical logic

Examination of McTaggart's Philosophy Vol. 1. By Dr C D. Broad Pp. lvi+460. (Cambridge: At the University Press, 1933) 21s net

ONE cannot do justice in a few sentences to this excellent commentary of McTaggart's philosophy. Not only is McTaggart himself a great philosophical mind, but Dr. Broad, his commentator, compels the attention of his readers whenever he writes about philosophy McTaggart's "Nature of Existence" is a difficult book to study. But its reading will perhaps become easier after perusal of the present commentary. With a wealth of detail and a great ingenuity of thought, Dr Broad shows us how McTaggart's analysis of existence and reality led him to the formulation of the principle of determining correspondence, and what masterly use he made of this principle in the explanation of metaphysical values. T G.

Fluorescence and Its Use as a Method of Testing and Analysis

By DR JULIUS GRANT

ONE of the results of the increasing popularity in recent years of so-called 'sun-ray' treatment has been the rapid development of improved methods of generating ultra-violet rays This has placed in the hands of the scientific worker very efficient sources of such radiation, and it is therefore not surprising that other uses of this region of the spectrum should have followed in the wake of the above developments One of the most interesting is the generation of a characteristic fluorescence in numerous substances, and this is now widely employed as a method of testing and analysis

The range of ultra-violet radiation is usually considered to extend from about 136 A to 4000 A, but the principal rays used for obtaining fluorescence effects are confined to wave-lengths between about 2500 A and 3700 A, and there is ample evidence that individual rays in this range are particularly effective Similar selectivity is, of course, well known in connexion with work on ultra-violet therapy and on the photochemical activity of ultra-violet light.

FIG 1 Fluorescence photograph of a forged document Arrows indicate original wording, which is not visible in daylight

GENERATION OF ULTRA-VIOLET LIGHT

Methods of generating ultra-violet light are fully treated in works on light-therapy, and it is necessary here only to indicate some of the special requirements of fluorescence analysis

Carbon and mercury arcs have both been used, but whilst the former is best adapted for fading tests on account of the similarity of its spectrum to that of sunlight, the latter has proved more popular where an intense ultra-violet radiation is required with a minimum of visible rays The character of the actual radiation emitted depends, however, on the type of lamp and on the working conditions As is well known, the principle of the method is the production of an electric arc in the mercury vapour produced between two heated mercury electrodes Mercury lamps vary considerably in design, some give a point-source and are particularly useful for spectroscopy and fluorescence microscopy, whilst others are designed to give a maximum luminous area The unstable open forms of U- or H-tubes have now largely been replaced by completely enclosed types, one of the latest of which takes the form of an ordinary electric-lighting bulb containing a globule of mercury and two tungsten electrodes which serve both to heat the mercury and to carry the arc

There are also rival claims between lamps operating in a vacuum and at atmospheric pressure The latter have a great advantage in that they can be opened and cleaned, but on the other hand, with the former there is less necessity for such cleaning, owing to the absence of air One well-known design consists of an evacuated quartz tube, with a reservoir of mercury at each end, into which protrude metallic leads connected to the electricity mains When the lamp is tilted, the mercury runs across the floor of the vessel and short-circuits the two leads, the heat so generated produces mercury vapour and the arc then strikes.

Such lamps were at one time expensive and deteriorated rapidly, but recent models are cheaper both to buy and to run, and can eventually be regenerated The changes which occur on ageing often produce alterations in the spectral distribution of the radiation, and if these are not controlled from time to time discordant fluorescence results may be obtained

During the last year or so, several 'lamps' which utilise the ultra-violet constituents of daylight have appeared. They are essentially darkened boxes fitted with a filter to remove visible rays, and are necessarily relatively inefficient However, they are portable and comparatively cheap, and for some purposes are adequate

TECHNIQUE

The lamp is usually housed in a box, provision being made for viewing objects either by reflected or transmitted light through a filter which removes visible rays, the brilliance of which would obviously mask any fluorescence Filters may be solutions of dyestuffs or coloured or coated glasses, and may be chosen so as to isolate almost any given range of wave-lengths; nickel oxide glass ('Wood's glass') is, however, the best for most purposes. As already indicated, it is important to keep a control over both the quality and quantity of the radiations, and here again there is a wide choice of methods, of which the photoelectric cell and the use of the selective photochemical action of the rays on certain chemical reactions are the most promising.

The procedure depends to a great degree on the nature of the sample. Useful information is often obtained if a little powder is blown on to moist filter-papers which have been treated with reagents, whilst solids in the mass are usually exposed on a fresh fracture which also may be spotted with reagents. Liquids are examined in non-fluorescent containers, preferably in open Petri dishes or in quartz test-tubes, and it is often an advantage with solutions to use a variety of solvents and dilutions. Capillary analysis, in which the 'zones' produced on a strip of filter paper suspended in the liquid or solution are examined in ultra-violet light, has proved very useful, notably in connexion with mixtures of alkaloids and dyes, and Danckwortt and Pfau[1] have even obtained semi-quantitative results in this way.

When, however, it is required to determine the composition of a mixture containing a fluorescent ingredient, the usual procedure is to match it against one of a series of known mixtures. The importance of working under strictly standardised conditions in all this work cannot be emphasised too strongly. The type of lamp, its age, the time which elapses after striking the arc, the filter, the temperature and humidity, etc., all determine the actual appearance of the fluorescence, and it is essential that each worker should evolve and adhere to his own conditions if apparent anomalies are to be avoided.

The use of fluorescent compounds as stains in microscopy and as indicators in titration work has greatly widened the range of application of the method. In the former case it is often possible to bring out fine details, for example, of plant structure, which are invisible in daylight, whilst the latter method may be used for coloured fluids, for example, for the titration of quinine[2] and of the acidity of wines, and for neutralisation titrations in extremely dilute solutions. Photographic methods require special technique and their applications are limited by the difficulty of reproducing colour effects. They are, however, greatly used in criminological and museum work, for example, to provide evidence of falsification of documents (Fig 1 is a photograph of a falsified document taken in ultra-violet light, in which the original writing is plainly visible, although not apparent in daylight).

APPLICATIONS

The applications of fluorescence are numerous and varied, and can only be briefly indicated here; they are discussed fully elsewhere[3].

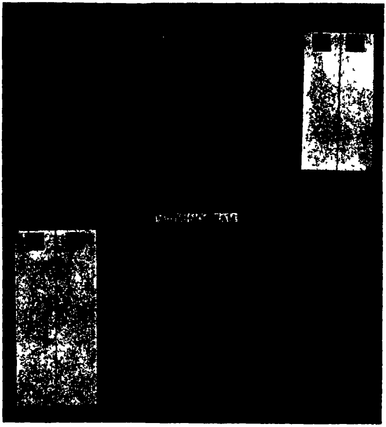

FIG 2 Comparison of daylight and fluorescence photographs of strips of yellow paper

The examination of chemical substances for purity is one of the best known. Many alkaloids, most dyestuffs and numerous inorganic and organic compounds give characteristic colours, and as these may depend on the origin, purity and method of manufacture, they form the basis of rapid testing methods, the importance of standardised conditions being always emphasised. Such methods have found application in connexion with paint pigments, drugs and all industries where dyestuffs are used. Thus in Fig 2 specimens 1–4 are strips of dyed yellow paper which appear identical in daylight (top row) but vary considerably in colour and in intensity in ultra-violet light (bottom row); Nos. 5 and 6 are the same as

No. 4 after exposure to sunlight (1 week) and to ultra-violet light (2 hours), respectively, and comparison of No. 7 with No 8 shows the effect of addition of wax size. Accelerated fading tests are best carried out with the carbon arc, which gives effects nearest to those of sunlight, in many cases the results from the mercury arc are definitely misleading and this lamp is more suitable for ageing tests, or for tests based on the use of the change in fluorescence on exposure (see Nos 5 and 6 in Fig 2) as a measure of stability

Plant materials offer a wide scope for the method, particularly if fluorescence microscopy is employed Examples are the differentiation of woods and of various strains of seeds, and the control of the composition of farm products such as fertilisers, poultry and cattle foods, dairy produce, etc Fig 3 shows the appearance in ultra-violet light of five rhubarbs (*R Palmatum*, High-dried Flats, Rough Rounds, *R Rhaponticum* and Canton, respectively), and is an example of the numerous applications of the method to plant drugs The fluorescence produced by bacteria, fungi, animal organs, sera and biological fluids also lends itself to the method, and a considerable amount of work has been carried out (notably by C Dhéré[4]) on blood and the porphyrins

FIG 3 Fluorescence photographs of five different rhubarbs

Closely related to this are applications to medico-legal work, particularly from the point of view of identifying stains on garments and drugs in body fluids, and although the method is in its infancy, it has already met with some encouraging successes

The method is also of considerable use in other branches of criminological work; erasures or alterations of written matter (see Fig 1) and the detection of imitation water-marks are examples, and in a case recently submitted to me[5], it was possible to differentiate easily between a genuine banknote and a particularly clever forgery from the fact that the dyestuff used to produce a blue design fluoresced with a green colour in one case but appeared black in the other.

Museum work should be mentioned in this connexion, since photographs in ultra-violet light of paintings, palimpsests and other documents frequently provide evidence of superimposition The dyestuffs used on postage stamps are excellent indications of possible imitations in philately, and a complete technique has been evolved for the examination of geological specimens and fossils. Since ageing influences the appearance of sculpture materials, ivory, woodwork, etc, repairs and imitations may be detected.

The application to work involving the use of organic solvents and mineral or essential oils is particularly wide, as such materials usually glow vividly in ultra-violet light Reference has already been made to the identification of dyestuffs and the use of fluorescent indicators, but it should also be mentioned that this work has provided useful information concerning the influence on fluorescence of chemical constitution.

In conclusion, the applications to the food industries merit a few words. Fatty foods fluoresce, the yellow colour of butter being modified by the presence of margarine or other foreign fats. A great deal of work has been carried out on milk, partly from the public health point of view and partly with the object of ascertaining the nature of the fluorescent constituent (lactochrome), which has now actually been isolated

The sensitiveness of micro-tests for organic or inorganic substances may often be magnified if the test involves the production of a compound which fluoresces, and several aids to the detection of preservatives such as boric, benzoic and salicylic acids, as well as sulphites[6], are provided in this way Other work has been directed to the examination of spices, cheese, jams and bakery and fermentation products, and among the confectionery products special mention should be made of honey[7], since applications of the methods of capillary analysis and absorption spectroscopy have yielded results which, it is claimed, enable a distinction to be made between honeys of different origins

No mention has been made of applications of the method to the rubber, cellulose, paint, fuel or ceramic industries, or to sewage disposal and general organic and inorganic analysis, but numerous applications suggest themselves, and the general utility of the method (provided always that working conditions are standardised) is now recognised

I am indebted to the British Hanovia Quartz Lamp Co, Ltd, for the loan of Fig 1, and to Messrs Chapman and Hall, Ltd, for Figs 2 and 3 (from "Fluorescence Analysis in Ultra-Violet Light") which were kindly photographed for me by Col W. R. Mansfield.

The Ray Society

THE recent appearance of the one hundred and twentieth volume of the publications of the Ray Society is a step onward in a great national undertaking. In the 'thirties of last century, the idea of producing a 'fauna' worthy of British science, in which every species of animal known to occur in Britain should be described and figured, with some account of its habits, habitat and synonymy, by the united labours of several naturalists, each an expert in his own line, was being realised under the sympathetic management of Mr Van Voorst. Yet in spite of the loving care that he lavished on the production, as is abundantly shown by the charming vignettes which adorn each chapter of his books, it became apparent to the naturalists who in 1843 attended the meeting of the British Association in Cork, that Van Voorst's series had begun with monographs which were 'best sellers', such as Bell's "British Quadrupeds" 1839, Yarrell's "British Fishes" 1836 and "Birds" 1843, and that there would remain a considerable residue of unmonographed classes of animals for which neither the British Association, nor the scientific societies, nor publishers would have the funds necessary for publication. "To rescue such precious materials from oblivion, is one of the objects for which the Ray Society was instituted."

The original proposal to found a "Ray Club", an association for publishing zoological and botanical monographs and translations "which would not be likely otherwise to find a publisher", was taken up by a considerable body of naturalists in response to a circular drawn up by George Johnston of Berwick-on-Tweed, and widely circulated by Sir William Jardine. Their replies are bound up in a volume of letters addressed to Sir William Jardine, recently presented to the Ray Society. Not all were enthusiastic. Botanists were on the whole inclined to the opinion that sufficient provision had already been made for the British flora, but Prof Charles Babington of Cambridge saw that in cryptogamic botany much remained to be done. Prof Richard Owen, quoting his experience of the early struggle of the Sydenham Society, at first refused to join the proposed club on the ground of the impossibility of getting enough members for the purpose. However, by dint of much correspondence, a sufficient body of subscribers was eventually secured, and on February 2, 1844, with a slight change of title, the "Ray Society" was instituted, and officers were elected, and on October 2, under the chairmanship of Sir Philip Egerton, the report of the first annual meeting was read by the secretary, Dr. Edwin Lankester. Four hundred members, including Prof. Owen, had been enrolled, £236 had been received in cash, and a programme of projected publications was issued; the first two being "Memorials of John Ray" and "Iconographia Linnæana or Illustrations of the original specimens in Zoology of Linnæus at present existing in the Museum of the Linnean Society", to be edited by Profs Bell and Forbes.

The second annual meeting was held at Cambridge on June 23, 1845, Prof John Phillips being in the chair.

Already in December 1843, "A Monograph of British Nudibranch Mollusca" was in preparation by Messrs Alder and Hancock; and a volume of "Reports on the Progress of Zoology and Botany" in 1841–42 was the first volume to be issued to the subscribers. Also the Council of the Society had plans for the translation of Aristotle on "Animals", Dioscorides on "Plants", Azara on the "Birds of Paraguay", and for a new edition of Linné's "Systema Naturæ".

None of these was attempted, though Johnston, who shared the secretarial duties with Dr Edwin Lankester, wrote: "I trust the Ray Society may publish a good translation of Aristotle and Pliny, but beyond these I hope we may have better fish to fry for a very long time to come." This hope has been most fully realised, for in its programme the Ray Society has gone from strength to strength.

The first great folio monograph to be undertaken was on the "British Nudibranch Mollusca". This continued to appear in parts for eleven years, and was completed by a supplementary volume fifty-five years later. Meanwhile, the high reputation of this folio series of monographs was firmly secured by the classic volumes of Allman on "Fresh-water Polyzoa" 1856, Huxley on "Oceanic Hydrozoa" 1859, Blackwell on "British Spiders" 1861–64, Carpenter on "Foraminifera" 1862, Gunther on "Reptiles of British India" 1864, Allman on "Gymnoblastic Hydroids" 1869–70, and McIntosh on "Nemerteans" 1873–74. They are not only scientific works of the first order, but also of artistic merit that had not been equalled.

The practice of publishing translations and reports on the progress of the biological sciences was discontinued after 1868. A high standard was also set in the series of octavo volumes. Charles Darwin's great "Monograph of Cirripedia" 1851–54, soon to be followed by Bowerbank's "British Spongiadæ" 1864, etc., put new life into the study of these groups. If we classify the various groups of organisms that have been monographed, we find them distributed as follows:

PROTOZOA: Foraminifera 1857, Rhizopoda 4 vols. 1905–18.

PORIFERA: by Bowerbank and Norman, 4 vols. 1864–79.

COELENTERATA: 1847, 1859, 1869–70; Sea Anemones 1927 and in continuation.

ANNELIDA: by McIntosh, Nemerteans, 1872–73; Polychæta, 1898–1921.

Fresh-water Polyzoa, by Allman 1856.

TRILOBITA: 1846.

CRUSTACEA: Entomostraca, 1849; Cirripedia, 1851–54, Copepoda, 1876–79; 1931–33; parasitic Copepoda, 1912–13.

ARACHNIDA: Oribatidæ, 1883–87, Tyroglyphidæ, 1901–3, Hydracarina, 1924–28.

INSECTA: Collembola and Thysanura, 1871; Aphides, 1875–82; Coccidæ, 1900–2, Orthoptera, 1919, Phytophagous Hymenoptera, 1881–92, Dragon-flies, 1930; Larvæ of Butterflies and Moths, 9 vols. 1885–99.

TUNICATA: 1904–12.

VERTEBRATA: Batrachia, 1896–97, Reptiles, 1863, Cetacea, 1866.

Among the botanical works are memoirs on Desmids, 1904–22, Diatoms, 1929; Charophyta, 1917–23, Lichens, 1851, and on Vegetable Teratology, 1868, 1915–6.

In the face of this successful record, it is now amusing to read a passage in one of Bowerbank's early letters to Jardine: "I have seen Owen this morning and find he is strongly opposed to us. I tried him very hard, but it was without effect. Never mind. His weight is not so great as you in the country may imagine, and I can see that we shall get on very well without him."

It is to be observed that although the majority of the volumes issued by the Society are concerned with the systematic description of the animals and plants of the British Isles, this was only one of the objects which the founders had in view, and from the first some of the publications had a wider scope. Some systematic monographs deal with Europe or India, or include the whole world in their survey, and there are occasional works on such subjects as morphology and teratology and on the historical and biographical aspects of the science.

When, as a boy, I stayed with my father at various country houses, I recall that frequent reference was made to the Ray volumes for the identification of unfamiliar forms of life. The library of a large country house would not have been considered as adequately furnished without these works of reference. Now, alas, owing to increasing specialisation, fewer and fewer people have time to be interested in the productions of their home-land, and it is therefore becoming more and more difficult to obtain support for scientific publications from individual subscribers. It has thus become the bounden duty of the public libraries to stimulate and provide for the public interest.

This account of the monumental achievement of the Ray Society must not be closed without some allusion to the fact that the earliest circulars and volumes issued by the Society in 1844 were printed by Messrs. C. and J. Adlard of Bartholomew Close, and that, although name and address have been modified, no other firm's imprint has appeared on the title pages for ninety years. Nor must we forget the very great services which have in recent years been rendered to the Society and to its authors by Dr. W. T. Calman in his editorial, no less than in his secretarial, capacity.

The agents for the sale of the Ray publications are Messrs. Dulau and Co. R. T. GUNTHER.

Obituary

PROF. T. SWALE VINCENT

DR. THOMAS SWALE VINCENT, formerly professor of physiology, University of London, died on December 31, 1933, at his home in Fishpool Street, St. Albans, at sixty-five years of age.

Born on May 24, 1868, the son of Mr. J. Vincent, Swale Vincent was educated at King Edward VI Grammar School, Birmingham, and took his medical course at the University of Birmingham, then Mason University College. After taking his degree, he went to the University of Heidelberg to study physiological chemistry under Prof. Kossel, and returned to Birmingham to take up his first appointment as demonstrator of physiology. The year 1894 had seen the birth of endocrinology as we know it to-day, with the discovery by Oliver and Sharpey-Schafer of the striking rise in blood pressure produced by the intravenous injection of an extract of the suprarenal capsules. Swale Vincent at once followed this new line of investigation, and pursued it through the whole length of his scientific career, with occasional excursions into the related fields of the circulation and of vaso-motor reflexes. In 1896 he published his first paper entitled "The Suprarenal Capsules in the Lower Vertebrates" in the *Proceedings of the Birmingham Natural History and Philosophical Society*. Soon afterwards he was appointed British Medical Association research scholar, and went to Sharpey-Schafer's laboratory at University College, London, where he continued his investigations. After two years he became Sharpey scholar in physiology, an appointment which carried with it the post of chief assistant in the physiology department, and later he was appointed assistant professor of physiology under Prof. Starling.

Swale Vincent left University College in 1900 to take up the post of lecturer in histology in the University of Cardiff. One of his students there was T. Lewis, now Sir Thomas Lewis, with whom he published two papers on the biochemistry of muscle. He left this post in 1902 to hold the Francis Mason research fellowship for investigating the physiology and pathology of the thymus and other ductless glands, and went to the Physiology Department of the University of Edinburgh which, under Sir Edward Sharpey-Schafer, had become an active centre of endocrinological investigations. He collaborated there with two advanced students, W. Cramer and W. A. Jolly, now professor of physiology at Cape Town. In 1904 he was appointed to the chair of physiology in the University of Manitoba, and remained in Winnipeg until 1920 He had to create an entirely new department there, a task which he performed so successfully that when he left Winnipeg to return to London as professor of physiology at the Middlesex Hospital, the University of Manitoba paid him a well-deserved tribute by conferring upon him an honorary LL D In London it again fell to his lot to reorganise the Department of Physiology, and its active scientific state when he retired in 1930 bears witness to the success of his efforts Swale Vincent was at various times examiner in the University of London and the University of Leeds, and also of the Conjoint Board. He had been secretary of the Ductless Glands Committee of the British Association since 1898 In Canada he served as a member of the Industrial Fatigue Board

Swale Vincent's numerous publications cover a large part of endocrinology. Beginning with a study of the suprarenal glands, he proceeded to investigations on the pituitary, the thymus, the thyroid and parathyroid glands, and the Islets of Langerhans He was a prominent representative of the Schafer school of physiology which, regarding the cell as a basic unit of physiological functions, combines histological studies with experimental technique The present generation of physiologists who can buy most of the various internal secretions in a more or less pure state at a chemist's shop, must find it difficult to realise the laborious investigations required to understand the morphological and functional relationships of the different parts of the endocrine organs, most of which are formed as a result of the joining up of histogenetically and functionally different tissues

In extending his investigations to the action of normal tissues other than endocrine organs, Swale Vincent discovered the existence of substances present in all tissues producing a marked lowering of blood pressure and different from choline One of these substances was identified later by Barger and Dale as histamine, the subsequent study of which in the hands of Dale and his collaborators has revealed its profound physiological significance. Swale Vincent was a careful worker, with a highly critical mind, qualities which enabled him to make positive contributions of lasting value, and to clear the new science of endocrinology from many pseudo-scientific weeds The high international reputation of his work found recognition in the request to write a series of reviews on the ductless glands for Ascher-Spiro's "Ergebnisse der Physiologie". These reviews were later expanded into a book "Internal Secretion and the Ductless Glands" which, first published in 1912 and since passed through three editions, is one of the standard works on the subject. He also published in 1924 an "Introduction to the Study of Secretion" and in 1929 with Prof. Sampson Wright, formerly his pupil and now his successor, "Introduction to Practical Mammalian Physiology".

Swale Vincent was a man of firm principles and high ideals on which he would not compromise. He was essentially a shy man, and this sometimes gave an impression of brusqueness, while to those who had the privilege of knowing him well he was a staunch friend and a charming companion He had a deep love and a great understanding of music and was himself no mean pianist. It was characteristic that in the last years of his active life he became interested in the study of the physiological reactions of the body to music. In 1914 he married Beatrice, daughter of Mr. W. Overton of London, who survives him, and had two daughters

W C.

Dr Knud Rasmussen

Knud Rasmussen, who died in Copenhagen in December last, devoted most of his life to the exploration of Greenland, particularly in regard to the ethnography of the Eskimo He was born in Greenland on June 7, 1879, the son of Chr Rasmussen, who was a pastor in that country and later a lecturer in the University of Copenhagen His mother was of Eskimo descent.

After taking his degree at Copenhagen, Rasmussen visited Lapland to study the natives and in 1902 returned to Greenland with M Erichsen to examine the social conditions of the Eskimo on the west coast. The report of that two years' study led to several reforms in the Danish system of administration, and in 1905 the Danish Government sent him again to Greenland to explore the conditions for reindeer as a source of livelihood for the natives From 1906 until 1909 he was in Greenland studying Eskimo folk-lore, and his visits to the isolated Polar Eskimo of the Cape Yuk area led to the foundation in 1909 of the mission station of Nordstjernen in North Star Bay The following year Rasmussen added a trading station and changed the name to Thule Afterwards the mission station was moved farther north, and Thule became the base for a long series of scientific expeditions under Rasmussen, in most of which he successfully used the Eskimo technique in travelling and hunting.

The first Thule expedition, in 1912, crossed the ice-sheet in the north-west to Danmark Fjord and Independence Fjord, thus linking the discoveries of Peary with those of Erichsen After spending some time in exploring around Thule and Melville Bay, Rasmussen led the second Thule expedition in 1916–18 to explore the topography and structure of the north-west coast. The return to Thule over the edge of the ice-sheet led to the death of the Swedish botanist, Th. Wulff, who succumbed to the hardships This expedition convinced Rasmussen that there can have been no migration of Eskimo round the north to the east coast of Greenland. Rasmussen did not take part in the third Thule expedition but devoted the fourth, in 1919, to a study of the folk-lore of the east coast Eskimo. The fifth Thule expedition, in 1921–24, entailed a journey, with K. Birket-Smith, from Greenland to Bering Strait through the whole extent of Eskimo territory with the view of studying the origin and evolution of

Eskimo culture. He found the oldest culture among the Caribou Eskimo, west of Hudson Bay. This spread to the arctic coasts and became dependent on marine animals, and then east and west until the Thule culture was homogeneous from Greenland to Alaska. An Alaskan culture, borrowing Asiatic influences, spread eastward as far as Greenland and is superimposed on the earlier culture. Rasmussen's researches on the Caribou Eskimo were a new chapter in ethnography.

With Denmark's increased attention to East Greenland subsequent to her suzerainty being established over the whole country, Rasmussen turned his attention to the east in the sixth Thule expedition of 1931. The aim was to explore the coast between Cape Farewell and Angmagssalik. Many additions to the charts were made and it was found that this part of the east coast is relatively free from ice in late summer. The seventh Thule expedition of 1932 was the largest that Rasmussen led. It was also the first on which he made aerial surveys. The work was the outcome of the previous year's reconnaissance and resulted in detailed surveys from Cape Farewell to Umivik, as well as two flights across the ice-sheet. Equally important was the archæological work on former Eskimo habitation of the coast. Rasmussen decided that seals were numerous enough to support a scattered Eskimo community. Hunters remained to investigate this problem more fully. It was from a resumption of this work that Rasmussen returned ill to Copenhagen last year.

Several of Rasmussen's works have been translated into English, including "The People of the Polar North" (1908), "Greenland by the Polar Sea" (1921) and "Across Arctic America" (1927). The reports of the various expeditions appeared in English and Danish in *Meddelelser om Gronland* and elsewhere. He also wrote several books in Danish including "Nye Mennesker" (1905), "Under Nordenvindens Svobe" (1906) and "Myter og Sagn fra Grönland" (1921–25). In all his works he had the happy faculty of combining a charming lucidity of style with a wealth of information. Among the many honours bestowed on Rasmussen were the Founder's Medal of the Royal Geographical Society, the Danish Medal of Merit and the orders of Dannebrog, St. Olav and the North Star.

R. N. R. B.

We regret to announce the following deaths:

Sir William Hardy, F.R.S., director of food investigation in the Department of Scientific and Industrial Research, secretary of the Royal Society in 1915–25, and president this year of the British Association, on January 23, aged sixty-nine years.

Dr F. L. Kitchin, F.R.S., palæontologist to H.M. Geological Survey of Great Britain, on January 20, aged sixty-three years.

News and Views

The Endless Adventure of Government

Problems of government and citizenship in the modern world were discussed by Mr Walter Elliot, the Minister of Agriculture, in his rectorial address as Rector of the University of Aberdeen on January 18. Government to-day, he said, is passing through a great transformation both at home and abroad. Governments and States are no longer merely geographical or political units, but economic units which every kind of intercourse has to take into consideration. Production is becoming decentralised; international trade less and less an interchange of specialised lines of production and more and more a competition in similar lines. The powers of modern science tend to make it feasible for specialised lines to be produced anywhere in the world, or to be replaced by others just as good; hence the national unit has become possible, although not necessarily desirable.

Interdependence of Various Countries

The formula of the continually increasing interdependence of the world requires qualification. Mr. Elliot gave three examples in illustration. In the first he traced the change in the economic aspect of the trade in nitrate for use as a fertiliser. In the nineteenth century a great trade was built up with South America; steel rails went out and nitrate came back. Large fortunes were made, international lending improved, and the economists were happy. But men of science, thinking it unnecessary to transport nitrogen to fields already supporting the pressure of a column composed mainly of that gas, found a means of producing it in Europe, which was good for production but bad for trade. Referring to the neon lamp, Mr. Elliot said it was the old lamp, and not the new, which demanded all the paraphernalia of nineteenth century economics; whilst the new artificial plastics derived from acetylene are replacing walnut and maple and the mahogany which took our forefathers to the West Indies. Mr. Elliot next turned to foreign investment, another section of the world's work where interdependence is no such certain sequence as was once assumed. A great deal of what is described as 'trade' is not exchange, but investment. The uneconomic nature of a great deal of foreign development has been masked by the free gift to competitors of transport systems, railway and steamer lines, which have been constructed at the expense of the producers in Great Britain and presented to their competitors.

Marketing Boards

The 'endless adventure of government, has become the problem of problems, the real riddle of the Sphinx. The reason is immediate fear—fear both of war and of peace. Organisation is essential; there are two methods—to organise the world at once, or to organise smaller units and gear them up to each other as soon as time and hard thinking will permit. Both methods are required. The States of the British Commonwealth of Nations have many economic problems in common, and the need of some standing organisation to examine these problems has been repeatedly felt. Mr. Bruce, formerly Prime Minister of Australia, has suggested that some of the best minds available should be applied exclusively to these formidable tasks, particularly in view of the emergence of British agriculture as one of the great and growing agricultures of the Empire. Mr. Elliot greatly hopes that the work will be undertaken. But an organisation which holds within itself the possibility of just such a development—the Empire Marketing Board—has within the last few months been brought to an end. The failure of some of these attempts, the difficulties of others, do not exonerate us from the necessity for making fresh trials. Let us try marketing boards to cover the United Kingdom if we cannot get one to govern the world, if we cannot get one to span the Empire. In agriculture we are working on the lines of self-government in industry. We are trying to reconcile the producers and the customers, the industrial and the political aspects of the nation, which can no more be separated than the front and the back of a man's head.

Another Large South African Diamond

A DIAMOND of fine quality was found in January by Jacobus Jonker in South Africa in the Elandsfontein alluvial diggings on a tributary of the Pienaars River, near the Premier diamond mine and north-east of Pretoria. The weight is given as 726 carats (145·2 gm.). There is no evidence to support the suggestion that this new 'Jonker' diamond is the missing portion of the 'Cullinan' diamond, which was found in 1905 in the yellow ground in the wall of the Premier mine at a depth of 18 ft. beneath the surface. The 'Cullinan' weighed 621·2 gm. (3106 metric carats), and, as shown by the large cleavage surface, it was evidently only a portion (perhaps rather more than half) of a larger crystal. Diamonds sometimes become fractured during the eruption of the kimberlite magma into the pipes. Other large stones, but of doubtful quality, have been recorded from the Premier mine, namely one of 1640 carats in 1912, another of 1500 carats in 1919, and another of 1195½ carats in 1924. The first of these weighings would be against the English carat of 205·304 mgm., and the last two presumably against the metric carat of 200 mgm. The next largest stone is the 'Excelsior' found in 1893 in the Jagersfontein mine in Orange Free State, which in the rough weighed 199·04 gm. With the older diamonds there still exists an unfortunate confusion in the weights when expressed in carats. The re-cut 'Koh-i-Noor', usually listed as 106$\frac{1}{16}$ carats, weighs 21·786 gm. or 108·93 metric carats. A mass of carbonado (a compact aggregate of small crystals of diamond) found in Bahia in 1895 weighed 630 gm.

Sir Hans Sloane's Collections

A TEMPORARY exhibit of a selection of minerals and botanical specimens and books from the Sloane collections is now displayed in a lighted case in the Central Hall of the Natural History Museum at South Kensington. It was these collections that formed the nucleus of the British Museum in 1753, and they contain many objects of considerable intrinsic value and of historic interest. A recent study of the voluminous MS. catalogues written by Sloane himself has led to the identification of many mineral specimens belonging to his collection. There is a good series of "pretious stones", including a magnificent Indian-cut sapphire weighing 31·5 carats, and a wonderful series of objects carved in agate, mocha-stone, carnelian, jasper, rock-crystal, nephrite, lapis-lazuli, etc. Most interesting are two drawers with the original labels from an old cabinet of minerals supposed to have medicinal virtues and listed as 'officinalis'. Sir Hans Sloane was a celebrated physician—it was he who certified the death of Queen Anne in 1714, and he succeeded Sir Isaac Newton as president of the Royal Society. One of the quaint entries in his MS. catalogue reads: "Lapis variolosus if hung about the Person makes the small Pox come favourable and hinders their being mark'd from its Signature". The Sloane collections were formerly in the old Manor House of Chelsea (built by Henry VIII), and his memory is preserved in a dozen streets, places, and squares named Hans or Sloane.

Indian Earthquake of January 15

A BRIEF notice of this great earthquake, based on the earliest reports, was inserted in our last issue (p. 94). Later accounts add considerably to the first estimates of the loss of life and of the extent of the disturbed area. It is clear that the number of deaths will amount to several thousand—in Monghyr alone, 4,000 are reported as killed. The epicentre, given by the seismographic records at Kew and Bombay, lies in lat. 26·8° N., long. 86·3° E., or a short distance to the east of the towns (Patna, Muzaffarpur, Monghyr, etc.) which suffered most from the earthquake. Thus, it would seem that the crust movement started a few miles east of Darbhanga and spread rapidly westwards for fifty miles or more. The distances from the epicentre of some of the places from which reports of the shock come are so great that it is only their close grouping that justifies their acceptance. Bombay is about 970 miles from the epicentre and Madras 980. Still farther to the south, and somewhat isolated, are Madura (1,250 miles) and Aloppey in Travancore (1,330 miles). If we assume the disturbed area to be bounded by a circle passing through Madras, it would contain three million square miles. The area included within the isoseismal of intensity 4 of the Kansu earthquake of December 16, 1920, was about 2½ million square miles, so that the area actually shaken must have been of the same order of magnitude as that disturbed by the recent earthquake.

Early History of the Reverberatory Furnace

AT a meeting of the Newcomen Society held on January 17, Mr. Rhys Jenkins read a paper on "The Reverberatory Furnace with Coal Fuel, 1612–1712". The term reverberatory, he said, came from the Low Latin "reverbero", to beat back; to-day, by reverberatory furnace, we mean one in which the material under treatment and the solid fuel are kept apart, and the flame and hot gases from the burning fuel enter the furnace proper at one end and are deflected or beaten down on to the material on the hearth by the roof of the furnace. The earliest account of such a furnace was given by Theophilus the monk, who wrote in the eleventh century. It was used for making glass. Early in the sixteenth century reverberatory furnaces were used in Germany for melting bronze for guns, but Agricola in his "De re metallica" makes no mention of them. The earliest description in the English language of a reverberatory furnace was found in a work published in 1613 by John Rovenson, while the earliest drawing of any value of a coal-burning reverberatory furnace was given by the German metallurgist Schluter in his "Grundlicher Unterricht von Huttenwerken" of 1738. During the seventeenth century the smelting of lead, copper and iron in reverberatory furnaces was attempted by various individuals at several places, the furnaces being generally without chimneys. An interesting point was when was it recognised that with a closed fireplace the air required for the combustion of the fuel could be drawn through by a chimney. The first record of the use of chimney draught is contained in Glauber's work of 1646 "Furni novi Philosophici", translated into English in 1651.

Petrie Portrait Fund

The retirement of Sir Flinders Petrie from the Edwards professorship of Egyptology at University College, London, has seemed to many of his friends an appropriate occasion for an expression of appreciation of his lifelong services to archæology. It is thought that this might most appropriately take the form of his portrait, to be presented to the College with which he has so long been associated. An appeal for funds for this purpose has been issued over the names of Prof. J. H. Breasted, M. J. Capart, Dr. Howard Carter, Prof. F. Ll. Griffith, Sir George Hill, Sir Henry Lyons, Dr. Allan Mawer, Sir Robert Mond and Dr. Margaret Murray. In issuing the appeal, it is pointed out that it is now more than fifty years since Sir Flinders began work as an archæologist at Stonehenge, and soon afterwards carried out the first accurate survey of the Pyramids at Gizeh. Referring to his influence on archæological studies during his long career as an excavator, the committee states no more than the bare truth when it points to his insistence on accurate observation and recording, and the stress he has laid on the significance of smaller finds, equally with the larger, in an excavation, in developing knowledge of the social conditions of the past. The appeal also refers to his early recognition of the importance of correlation in studying the intercourse between the various peoples of the Near East from earliest times. Finally, in attributing to him in large measure the awakening of modern interest in archæology, mention is made of the great number of archæologists who have achieved distinction after receiving their training and inspiration from him as lecturer and excavator. Subscriptions towards the fund will be received by Sir Henry Lyons, F.R.S., 3 York Terrace, Regent's Park, London, N.W.1.

Infra-Red Photography as an Aid to Navigation

The United States liner *Manhattan* has recently been fitted with a special look-out camera intended for an investigation of fog penetration with infra-red sensitive materials. Mechanism for the automatic developing and fixing of the photographs is included in the body of the camera itself, and the photographic record may be viewed one minute after the exposure has been made. The weather conditions encountered by the *Manhattan* since the new apparatus was installed have not been suitable for experimental work, so no records obtained under service conditions are yet available. The problem of fog penetration is not at all simple, and it remains to be seen whether the degree of penetration actually obtained by this method will be really helpful to navigators.

The Gases of the Atmosphere

In his presidential address before the Royal Meteorological Society at its annual general meeting on January 17, Prof. S. Chapman discussed "The Gases of the Atmosphere". The permanent gases of the atmosphere (mainly nitrogen and oxygen) are known, from direct measurements in the stratosphere, to be in constant proportions up to the greatest heights yet attained by Piccard and his successors in stratospheric flight. Other constituents vary in their concentration, because of processes tending to produce and destroy or transfer them in the atmosphere: among such constituents are water, ozone and the newly discovered positrons, which enter the atmosphere from outside as cosmic rays. Experiments were suggested to determine the rate of large-scale transfer of such gases by turbulence, using some easily detectable gas, artificially introduced, as an 'indicator'. Such experiments might also be made using ozone as the indicator, which would throw light on the distribution of ozone, as recently estimated by Dobson, Götz and Meetham. The possibility of removing the atmospheric ozone above certain ground areas was also considered. The absorption of solar radiation by oxygen and ozone was discussed in the light of new experimental data, and in relation to the composition and temperature of the upper atmosphere.

London's Underground Railways

By the formation of the London Passenger Transport Board last year, the unification of the underground train, bus, trolley-bus and tram systems of London has been accomplished. The British Electrical and Allied Manufacturers Association (Beama) has recently published a well-illustrated book giving an account of the part played by British manufacturers in providing machinery and equipment for this great transport service. The account given proves the sound administrative qualities of those who have made London's 'Underground' the foremost institution of its kind in the world. So far back as 1846, the prospectus which led to the foundation of the

Metropolitan Railway was issued, the object being to encircle the metropolis with a tunnel The scheme, of which Mr Charles Pearson, a city solicitor, was the author, was at first received with derision, and it was not until 1863 that the first section of the line, from Farringdon Street to Bishop's Road, was opened. The seven stations which formed this line have now increased to 226, and considerably more than a million passengers per day are carried Every weekday, 2,800 trains pass through Charing Cross station After forty years of steam, the Metropolitan and the District Railways were equipped for operation by electricity The great extension of London's underground railways and the equipment for electrical operation of the older steam lines was started in 1902 by the formation of the Undergound Electric Railways Co of London, Ltd., the site for the generating station being in Lots Road, Chelsea The great success of the undertaking is due to the recognition by the administration of the fact that the position is continually changing and that progress cannot be checked or thwarted in a living organisation

THE Lots Road Station is situated on the bank of the Thames at Chelsea and is well known to Londoners The amount of power generated per square foot of engine room area is six kilowatts, which is the highest figure for Great Britain The Neasden power station near Wembley Park supplies nearly 100,000 kilowatts, which is a third of that supplied by Lots Road The original plant was designed to operate with a steam pressure of 180 lb per sq in and a temperature of 550° F. , the present plant operates at a pressure of 265 lb. per sq in and 750° F. To supply the condensers with the necessary water, four artesian wells were sunk to depths varying between 400 ft and 600 ft and these yield about 18,000 gallons her hour After passing through the condensers, the water is cooled in wooden towers and utilised over again The electric transmission of energy is on the three-phase system at 11,000 volts, and many hundreds of miles of three core cable at this pressure are used The distribution voltage on the track is 630 direct current, the alternating current being converted to direct current either by rotary converters or mercury arc rectifiers The first escalator was installed at Earl's Court Station in 1911, and wherever escalators have been installed there has been a notable increase in the traffic In the event of any interruption to the train service, precautions are taken that there will be no delay in the issue of instructions to all sections concerned. At such points a loud speaker is installed and emergency messages are received from a central microphone in the control room at Leicester Square station

International Congress of Anthropology and Ethnology

ARRANGEMENTS are now well advanced for the first session of the International Congress of Anthropological and Ethnological Sciences, which will be held under royal patronage in London on July 30–August 4 next. The proposal to hold a congress of this nature was first made in 1912, when the International Congress of Americanists met in London, but the meeting in 1916, for which arrangements were then made, had to be postponed indefinitely owing to the War In future the Congress will be held every fourth year, alternating with the International Congress of Archæological and Proto-historic Sciences, which will be held in the second of the intervening years The Anthropological Congress will coincide with the meeting in Europe of the International Congress of Americanists, which this year is to be held at Seville The sessions of the Congress will be held at University College, Gower Street, and at the Wellcome Historical Medical Museum. The president is Lord Onslow and the chairman of the executive committee, Capt T A Joyce Prof J. L Myres and Mr A H. Brodrick are the joint honorary secretaries and Mr H G Beasley the treasurer Presidents of sections are Prof G Elliot Smith (Anatomy and Physical Anthropology), Mr F C. Bartlett (Psychology), Prof C B Fawcett (Demography), Dr. A C Haddon (Ethnography), the Rev. E. Smith, president of the Royal Anthropological Institute (Subsection of African Ethnography), Mr H Balfour (Technology), Prof C G. Seligman (Sociology), Prof E O James (Religions) and Dr. Alan H. Gardiner (Languages and Writing) Among the vice-presidents are the Archbishop of Canterbury, the Lord Mayor of London, the High Commissioners of India and South Africa, Sir James Frazer, and the presidents of the Societies of Antiquaries, the Folklore Society and the Royal Asiatic Society Particulars of the Congress may be obtained from the Royal Anthropological Institute, 52 Upper Bedford Place, W C 1

Archæology and Unemployment in the United States

IN the United States advantage is being taken of the funds available for the relief of unemployment to carry out certain archæological investigations which hitherto, although considered of great importance, have been regarded as too costly for the resources of the Smithsonian Institution, Washington The funds are to be provided by the Civil Works Administration and about one thousand men of the local unemployed will be engaged for the work of excavation. According to an announcement issued by the Smithsonian Institution, six Indian mound sites, each considered to be key positions in an archæologically unknown area, are to be explored In each case the work will be carried out under the direction of an official of the Bureau of American Ethnology. Three sites in Florida will be in charge of Mr Matthew W. Stirling, chief of the Bureau, one of these being an extensive system of pre-Seminole mounds and earthworks near Lake Okechobee which was discovered in 1931 , Dr F H H Roberts, Jr , will excavate a group of mounds in the Shiloh National Military Park at Pittsburg Landing, Tennessee , and Dr W F. Strong will be in charge of the exploration of a large mound six miles from Taft, Kern County, California, one of the key sites of Californian prehistory, which is known to have been abandoned soon after the first Spaniards reached the country At Macon, Georgia, a mound thought to be the site of an ancient Hitchi village will be explored. While deploring the circumstances which have made these undertakings possible, archæologists welcome the expenditure of funds in this direction, which, it is hoped, will at least make a beginning in putting the archæological exploration of the south-eastern States on the same systematic basis as the exploration of the south-west.

Coventry Libraries

THE Coventry Libraries and Museum Committee's report on the work of the year 1932–33 gives evidence of vigorous growth of the services under its care The Committee fosters the closest possible contact between the libraries and all activities of a cultural character, and is providing additional accommodation for such activities adjacent to its central library, where already during the past year meetings of societies devoted to the study of art, history, natural history, the drama, engineering, bee-keeping, etc, numbered 271, including 120 meetings of groups for the discussion of broadcast talks Among the most popular of the subjects of these discussions was "Biology and Everyday Life" Provision of books for children through the school library system, serving 55 schools and supplementing the activities of the special junior departments of the libraries, accounts for one sixth of the total issues Through the West Midlands Regional Library Bureau, the resources of many libraries in other parts of the country were drawn upon by way of temporary loans to meet special requisitions By the circulation of publicity material among branch libraries, the maintenance of a variety of book displays throughout the system was ensured Some of the most popular displays related to cooking, wireless, gardening, polar exploration, holiday literature, modern drama and home decoration. Among other services successfully maintained are the *Coventry Bookshelf*, a monthly medium of communication with readers; an "Illustrations Collection" of 15,000 pieces, a "lucigraph" for making facsimile copies of maps, prints, drawings, etc, a commercial and technical intelligence service, equipped with up to date indexes to practically all technical material published throughout the world, patent abridgments, consular and diplomatic reports, etc, and frequent exhibitions of material relating to matters of special local or regional importance.

Reform of Medical Education

IN his Bradshaw lecture recently delivered before the Royal College of Physicians, Dr C. S. Myers discusses the education of the medical student from the point of view of the industrial psychologist. As regards pre-medical study, which consists of physics, chemistry and biology, he considers that far more time is spent in practical work on such subjects than is necessary for those who are not going to specialise in any of them, especially as they have no educational value for the future doctor. A similar criticism is directed against the enormous amount of detail in anatomy and physiology required of the student, whereas little attempt is made at this stage to gather anatomical information from the corpse in the post-mortem room The student derives his knowledge of human anatomy mainly from dissection of the cadaver, in which the desiccated organs have lost their form and their relations in the living body. As a remedy for these and other defects in medical education, Dr Myers makes the following suggestions. In the first place, the student should spend part of his time in the wards as soon as he begins to study anatomy and physiology. Secondly, during the hospital period, he should receive a more complete education in the whole range of medicine and surgery before he attends the specialist departments. Thirdly, some training in the recognition and treatment of psychoneuroses is necessary for the future general practitioner, who is too liable to mistake the true nature of such conditions Lastly, before entering into general practice, he should serve an apprenticeship between the passing of the qualifying examination and the actual conferment of the diploma or degree.

Australian Meteorological Data

THE Council for Scientific and Industrial Research of the Commonwealth of Australia has published valuable meteorological statistics under the title "Meteorological Data for Certain Australian Localities" (Pamphlet No 42, Melbourne, 1933) A foreword explains that, for some time past, various investigators on the Council's staff had made extensive use of unpublished data collected by the Commonwealth Meteorological Bureau, in connexion with researches in soil science, entomology, plant industry, animal health, etc, and it was thought worth while to make such information more accessible to investigators by publishing selected data. The matter was discussed with the Meteorological Bureau, and it was agreed that the Bureau should provide the data and arrange the material in a form suitable for publication, while the Council would bear the costs of publication This pamphlet is the result of the co-operation of those two bodies. It gives in tabular form, for several hundred stations in Australia and Tasmania, mean monthly and annual values of daily maximum and minimum temperature and relative humidity, and average monthly and annual totals of rainfall. These averages refer to periods of varying length, as a rule not less than 15 years, and in not a few cases between 70 and 80 years. In the rare cases where the period is only five or six years, the figures may—especially in the case of such a variable quantity as rainfall—depart considerably from those that would be found over a suitably long period, but this drawback is nearly always met with in meteorological statistics for sparsely populated countries, and recourse must be had to such short records if large areas are not to be left unrepresented. A large folding map is attached at the end of the publication, which gives the meteorological divisions adopted by the Bureau and shows many of the stations included in the tables

Eugenics in Vera Cruz

IN December 1932 a new eugenic law was enacted in the State of Vera Cruz, which has the largest population in Mexico. A Bureau of Eugenics and Mental Hygiene was organised as a part of the

Health Department of the State. This Department has been engaged in eliminating smallpox and yellow fever, and has also greatly reduced the frequency of hook-worm, its sanitary services being in co-operation with the Mexican Government and the Rockefeller Foundation. The new Bureau is thus included in a public service and has large powers. Free birth control clinics were instituted, and sterilisation provided for in serious cases of unfitness and inadaptability. This is the culmination of a series of reforms made by Governor Tejada, which included the suppression of saloons, compulsory sex education in the schools, mandatory medical treatment for venereal disease and a new civil code which entailed eugenical provisions in matters of marriage and divorce. By the new regulations, which are given in full (*Amer. J. Psychiatry*, 13, No. 2) by Dr. S. Mendoza, who drafted the bill, provisions are made through the Bureau of Eugenics and Mental Hygiene not only for the dissemination of information but also for the control of sterilisation of persons suffering from hereditary diseases or from conditions which the Bureau considers to be "a cause of biological degeneration or mental deficiency in their offspring".

Association of American Geographers

THE thirtieth annual meeting of the Association of American Geographers was held on December 26-28, at North-western University, Evanston, Illinois. In the three day session fifty-seven papers were presented, including thirteen in the field of geomorphology, ten or more in regional geography and six in urban geography. The remainder represented a diversity of subjects. The afternoon of December 26 was devoted to the general subject of "Conventionalizing Geographic Investigation and Presentation". The papers on this subject were presented by Profs. P. E. James of the University of Michigan, Wellington D. Jones of the University of Chicago and V. C. Finch of the University of Wisconsin. A feature of the meeting was an address by Dr. L. Dudley Stamp, an invited guest of the Association, who spoke on "One Hundred Years of Change in Land Utilisation in the British Isles—the Work of the Land Utilisation Survey of Britain". The retiring president, François E. Matthes of the United States Geological Survey, gave the annual address. He spoke on "Our Greatest Mountain Range, the Sierra Nevada of California". The following officers were elected for 1934: *President*, Dr. W. W. Atwood, president of Clark University; *Vice-President*, Prof. V. C. Finch, chairman of the Department of Geography, University of Wisconsin; *Secretary*, Prof. F. E. Williams, University of Pennsylvania; *Treasurer*, Prof. R. S. Platt, University of Chicago.

Greenkeeping Research

THE autumn volume (No. 9) of the *Journal of the Board of Greenkeeping Research* contains a useful summary of experimental and practical results on the use of sulphate of ammonia and sulphate of iron as fertilisers and weed killers for lawns. It is interesting to note that the treatment has stood the test of several years' practical application, but its effects cannot be ascribed directly to increase in the acidity of the soil. Dr. F. T. Bennett describes a disease of turf known as *Fusarium* patch. The Director of the Board's Research Station at St. Ives, Bingley, Yorks, Mr. R. B. Dawson, contributes the fourth of a series of articles on "Common Weeds of Turf", whilst other members of the staff write on "A Greenkeeper's Guide to the Grasses" (Mr. I. G. Lewis) and "Composts and Fertilisers in Relation to Greenkeeping" (Dr. T. W. Evans). A new form of steriliser for killing weed seeds in compost which is to be applied to weed-free turf is described by Mr. K. M. A. Enthoven, of Hilversum, Holland. The subject matter of the whole volume is of great interest—almost a necessity—to golf green keepers, but the more general horticulturist will find a great deal of definite teaching which will help him to make his lawns the beautiful stretches of green sward which he so earnestly desires.

Scientific Horticulture

THE "Horticultural Education Association Year Book", vol. 2, 1933 has just appeared under the able editorship of Mr. R. T. Pearl (Wye, Kent: H. E. A., South-Eastern Agricultural College, 3*s.* 6*d.*). "Commercial Horticulture in Lincolnshire" is described by Messrs. J. G. Murray, F. Wakerley and J. C. Wallace, whilst Mr. D. V. Howells writes on the same topic for Scotland. Various aspects of fruit-growing are dealt with by Messrs. N. B. Bagenal, W. G. Kent, F. Kidd and C. West, B. S. Furneaux, R. Hart and A. J. Wooldridge. Dr. R. N. Salaman contributes a paper on potato virus diseases, Mr. C. A. Cameron Brown reviews early progress in electric soil heating, Dr. R. M. Woodman writes on weed killers, Mr. R. K. MacDowall on spraying with sulphuric acid, Mr. W. E. H. Hodson on chrysanthemum eelworm, and Mr. F. A. Secrett on "Early Market Garden Produce". Direct problems of teaching are discussed by Messrs. W. H. Christian and R. T. Pearl, whilst the presidential address by Mr. N. B. Bagenal is a biography of Thomas Andrew Knight. A valuable series of book reviews is added. The whole volume is a pleasing blend of science with practice.

Fossilised Tree Remains in Yellowstone National Park

SCIENCE SERVICE, Washington, D.C., has recorded an interesting discovery made during the construction of a new road from Tower Falls to Mammoth Hot Springs in Yellowstone National Park. While cutting through a rock, two petrified tree-stumps, both upright as they stood, the report says, millions of years ago, were brought to light. The progress of the new road has left the specimens cut in halves, embedded in the solid rock, which was probably volcanic dust when petrification was taking place during the Miocene period. It is even possible to trace the complicated root systems of the specimens. It has not been decided what species the remains represent. Chestnut, sycamores, sequoias, pines and cypress have all grown in this region during the centuries in which the fossilisation took place.

The Qattara Depression and Water Power

In a note in Nature of December 23, 1933, p 960, on Dr J Ball's paper in the *Geographical Journal* for October on the utilisation of the Qattara depression for water power, a misprint occurs in the estimate of distance that the power would need to be transmitted to the Nile delta This figure should be 150 miles, a distance over which water power could be readily transmitted, whereas the distance from the Aswan dam to the delta is 560 miles

Zoological Society of London

At the monthly general meeting of the Zoological Society of London held on January 17, it was stated that the total number of visitors to the Society's Gardens at Regent's Park for the year up to the end of December was 1,557,791. The number of visitors to the Aquarium during the same period was 263,438 At Whipsnade Park the number of visitors during the year was 433,429

The Night-Sky in February

Mercury reaches its greatest eastern elongation on February 18, when it will set an hour and ten minutes after the sun It is not easy to see this planet, but a sharp look out just after sunset in a situation where there is a good view of the western horizon may be rewarded. There will be no risk of confusion with Venus, which passes through inferior conjunction on February 5, and will not be visible in the evening sky after that date for several months, though it will be a brilliant object in the early morning sky just before sunrise. Mars is getting near the sun On February 18 it will set twenty-two minutes before Mercury, and will be practically invisible in the glare of the sunset Jupiter can be well seen in the early morning In February it will rise at about 10 p m. Saturn will be too near the sun for observation. It passes through conjunction on February 8.

Announcements

The Council of the South Wales Institute of Engineers has awarded the Institute's Gold Medal to Prof. A. E. Trueman, of the Department of Geology, University of Bristol, formerly of University College, Swansea, for his paper, "A Suggested Correlation of the Coal Measures of England and Wales", as being the most valuable paper received and published during 1933.

The Committee of the Cancer Hospital (Free), Fulham Road, London, has awarded a scholarship of the value of £100 per annum to Mrs Boyland in recognition of her services in the Research Institute of the Hospital She has investigated with Dr E Boyland the respiration of normal and cancerous tissues in the presence of derivatives of cancer producing compounds, and will continue the development of this work

The Secretary to the Minister of Health has announced that Sir Frederick Gowland Hopkins, Prof E. P Cathcart and Prof. Edward Mellanby, as physiologists representing the Minister's Advisory Committee on Nutrition, will confer with Prof. V H. Mottram, Prof S. J. Cowell and Mr G. P. Crowden, as physiologists representing the British Medical Association Committee on Nutrition, in regard to the differences which appear to exist between the two Committees on the question of the amount of calories and first-class protein appropriate as a basis for suitable diets

At the annual general meeting of the Royal Meteorological Society held on January 17 the following officers were elected for the ensuing year — *President*, Col Ernest Gold, *Vice-Presidents*, Mr David Brunt, Prof Sydney Chapman, Mr Francis Druce, Dr A Crichton Mitchell, *Treasurer*, Mr. R A Watson Watt, *Secretaries*, Dr J. Glasspoole, Mr W M Witchell, Mr. M McCallum Fairgrieve; *Foreign Secretary*, Capt C J P Cave, *New Councillors*, Dr A J Bamford, Mr M G Bennett, Mr I D Margary.

The following officers of the Royal Microscopical Society have recently been elected: *President*, Prof. W A F Balfour-Browne, *Vice-Presidents*, Mr J E Barnard, Mr Conrad Beck, Prof D M Blair, Dr G M Findlay, *Hon Treasurer*, Mr. C F Hill, *Hon Secretaries*, Prof R T Hewlett, J Smiles, *New Members of Council*, Dr A S Burgess, Dr R. S Clay, Prof R Ruggles Gates, Dr G S Sansom, *Hon Librarian*, Dr Clarence Tierney, *Hon Curator of Instruments*, Mr W E Watson Baker, *Joint Hon. Curators of Slides*, Mr N I Hendey, Mr. E J Sheppard.

Messrs Longmans, Green and Co, Ltd, hope to publish shortly the first of two supplementary volumes of Thorpe's "Dictionary of Applied Chemistry" This volume will contain subjects up to and including those coming under the letter M and the second will cover the remaining letters of the alphabet and include an index. The present editors, Profs J Thorpe and M A Whiteley, have preserved continuity and the traditional connexion of the "Dictionary" with the Royal College of Science.

Applications are invited for the following appointments, on or before the dates mentioned —A junior scientific officer in the Wood Chemistry Section of the Forest Products Research Laboratory, Princes Risborough, Buckinghamshire—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S W.1 (Jan. 29). A chief instructor in the Engineering Workshop of the Polytechnic, Regent Street, London, W 1—The Director of Education (Feb 5). A woman pharmaceutical chemist to the Gloucester County and City Mental Hospitals—The Medical Superintendent, County Mental Hospital, Gloucester (Feb 7). A junior engineer for the Safety in Mines Research Board—The Under-Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, London, S W 1 (Feb. 10) A lecturer in physiology in the University of Leeds—The Registrar (Feb 19) A senior botanist in charge of the Cereal Sub-Section of the Botanical and Plant Breeding Section of the Ministry of Agriculture, Egypt—The Under-Secretary of State, Ministry of Agriculture, Cairo (March 15). A professor of economics at Raffles College, Singapore—The Secretary, Universities Bureau of the British Empire, 88A, Gower Street, London, W C 1

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Activity of Crystalline Preparations of Vitamin B_1

IN the same laboratory where thirty years ago Eykman made his famous investigations, Jansen and Donath[1] succeeded in 1926 in obtaining for the first time the antineuritic vitamin in crystalline form, in quantities too small, however, for further study. Five years later, the same results were also obtained by other investigators; almost simultaneously there appeared publications on the same subject by van Veen[2], Windaus and Tschesche[3] and Ohdake[4], whose crystalline products were only slightly more active than that of Jansen and Donath, although at first the contrary was stated[5] Moreover, all these substances had roughly the same empirical formula, though they had been isolated from different sources —rice-bran and yeast.

This uniformity of results was broken by an announcement of Peters[6] and his collaborators, that they had isolated a still more active product. As a matter of fact, we were able to demonstrate in this laboratory that Peters' substance was about 1½ times as active as our purest product (and also Windaus's) The experiments were made with a kind of rice bird[7] These rice bird tests, which can only be made in Java (this being the one region where these birds occur), have the advantage that one works simultaneously with ten of these birds, which are very sensitive to a B_1 vitamin shortage and give very constant results Whereas about 0 5 mgm. of the original preparation of Jansen and Donath was needed to provide ten birds during about 25 days with the necessary B_1 vitamin (not a single case of polyneuritis occurring within 15 days), the necessary quantity of Windaus's and also of our preparation was 0 4 mgm., while of Peters' preparation only 0 3 mgm. was required.

By improvements of our method of isolation[8] applied thus far we have succeeded in isolating a crystalline product, which is about twice as active as our former preparation and then probably also more active than Peters' preparation; namely, 0 2 mgm sufficient for the rice bird test Of this preparation a rice bird therefore needs a daily dose of 0 8 γ, a young rat 1·5 γ or a little more. 1 gm. of this preparation is equal in activity to about 500,000 (provisional) international standard units The crystals are much flatter than those of the less pure preparations; the melting point is about 2° higher. Also its behaviour to different reagents is as described before[5]. The empirical formula is also similar to that of the less pure preparations from this laboratory (C, 40·7 per cent; H, 5 5 per cent; N, 15·7 per cent; it also contains sulphur). Hence it appears probable that the less active preparations contain inactivated vitamin, and the possibility is not excluded that even the most active preparations now obtained still contain inactive substance.

The 'activated clay' from this laboratory (which serves also as the League of Nations standard preparation) is a substance easily prepared in large quantities, and the isolation of the crystalline vitamin is a rapid process. In our opinion it is urgent that the investigation of this important vitamin should be made by numerous laboratories, in order to obtain definite results as soon as possible. We shall shortly publish elsewhere a detailed account of the improved technique for its isolation.

The Unit Character in Genetics

IN his British Association address on "The General Nature of the Gene Concept"[1], Prof. R. Ruggles Gates states that "the conception of the unit character was given up many years ago". It is hard to let this fertile conception go without a word to be said for it, even though it may be ineffectual. If the conception of the unit character is not wholly true in its original connotation, it cannot be wholly false since man himself has been spoken of as a "rational animal", denoting an individual unit of the highest degree of complexity The cuticular bristles of arthropods are structures of their own kind, that is to say, they are homologous, whether transformed into tactile, olfactory, natatory setæ, supporting spines or prehensile hooks They may be regarded as units of the first order, although they possess such different potentialities, to which may be added the qualities of position, colour and size

In the district of Mille Isles, situated in a part of the province of Quebec where the Laurentian Hills begin to sink down to the level plain of the St. Lawrence basin, I have recently picked up from the snow a dipterous insect destitute of its two wings. There are several kinds of 'flies' to be found on snow in late autumn and early spring, but only one of them is wingless, namely, *Chionea* Through the kindness of Mr Arthur Gibson, Dominion Entomologist, I have been supplied with a list of Canadian records of *Chionea* These are few and far between, but they go back to the time of P. H. Gosse (1839) When seen moving with its long legs slowly and somewhat helplessly on the snow, it presents at a distance a spider-like appearance, and the species found in Germany was named *Chionea araneoides*. The wings have simply ceased to be, they have dropped out of existence at a plunge, but the balancers or 'halteres', which represent the hind-wings of the two-winged flies, are maintained in full working order. The wings of a fly behave as a unit, but they have many accessory characteristics, chief among them being the venation. Nevertheless the wings not only function as a unit but in *Chionea* they have also vanished as a unit, while the balancers remain in full force.

The finding of *Chionea* in the flesh is a rare experience not easily dismissed from the mind The lesson of it is the persistence of vestigial organs, when modified to serve a new function, after the normal organs of flight have disappeared without a trace. There are plenty of flightless female moths lying dead upon the snow at this season; before the snow sets in they are to be found clinging to the trunks of trees; some of them have rudimentary scaly wing-pads. There is a distinction to be drawn between mere loss of the power of flight, as in the female silkworm moth, reduction of wings, suppression of wings and phyletic loss of wings. But for the absence of its wings, *Chionea* is a normal dipteron with compound eyes and primitive segmentation of the body. As indicated above, the smallest units have a collective value and it is probably in the sense of absolute indivisible units that the conception of the unit character has been abandoned by geneticists.

[1] NATURE, 132, 768, Nov. 18, 1933.

IN my address on the gene concept, part of which appeared in NATURE of November 18, I was discussing the subject particularly from the cytological point of view. Prof. Willey, in his interesting letter, has in mind another aspect of the unit character conception which I consider is of great importance from a phylogenetical point of view. When I said that "the conception of the unit character was given up many years ago", I meant that the early conception of a strict one-to-one correspondence between a particular character and a particular factor or gene, is no longer tenable. Studies of the interactions of genes and the multiple effects of single genes in development of the organism show (1) that many genes may contribute to the final production of single characters, and (2) that single genes may have multiple effects in the organism. While these are now well known principles in genetics, nevertheless it remains true that each gene usually has a preponderating effect in the production of a single character.

Cases such as the wingless species, to which Prof. Willey refers, may be the result of single mutations, like some of the *Drosophila* mutations which are in a more or less completely wingless condition. The literature of systematic botany and zoology abounds with cases of a similar kind, where the natural interpretation is that a unit gene mutation has resulted in the sudden loss or marked change of a single character. The investigation of such cases opens up a vast field in which the systematists and geneticists could co-operate, but unfortunately until now comparatively little has been done in this direction.

Variation du Rayonnement cosmique suivant la Latitude

LES études de la variation du rayonnement cosmique suivant la latitude (Clay, Compton et collaborateurs, Hoerlin) ont été effectuées jusqu'à présent avec la méthode des chambres d'ionisation; ces mesures ont montré l'existence d'un minimum de l'ionisation par rayons cosmiques dans les régions équatoriales.

Nous avons pensé qu'il serait bon de faire des mesures sous différentes latitudes, non de l'ionisation globale, mais du nombre de corpuscules pénétrants formant la partie directement décelable du rayonnement cosmique. Cette étude peut se faire avec des compteurs de Geiger-Müller montés en coïncidence.

Trois appareils, comportant chacun un dispositif de trois compteurs cylindriques superposés avec un sélecteur de coïncidences, un amplificateur et des relais, ont été emmenés dans un voyage Le Havre–Buenos-Aires et retour. Ils ont enregistré le passage des corpuscules ionisants pendant toute la durée du parcours, soit deux mois. Le nombre total de corpuscules enregistrés dépasse 100,000. Les résultats montrent une baisse régulière en fonction du temps que la comparaison des mesures à l'aller et au retour a montré être sensiblement linéaire; cette baisse due à une lente altération des appareils peut-être éliminée en faisant chaque fois la moyenne des mesures faites à l'aller et au retour aux mêmes points. On obtient ainsi les points figurés (Fig. 1) où les ordonnées représentent, à un facteur près, les nombres de particules traversant les compteurs en 1 heure, et les abscysses les latitudes des lieux d'observation. Les points marqués + sont relatifs à un appareil portant un filtre de 20 cm. de plomb. Les points marqués ○ sont relatifs à un appareil sans filtre, à compteurs proches. La courbe tracée présente un minimum dans la région de l'équateur. Le nombre de corpuscules pénétrants arrivant sur la terre à l'équateur est d'environ 15 pour cent inférieur à celui des corpuscules arrivant sous la latitude 40° (nord ou sud). Ceci est en concordance avec la diminution de l'ionisation globale observée, et montre que cette ionisation, qui peut-être due en partie à des rayonnements secondaires mous, suit bien le nombre de particules pénétrantes. Des mesures avec inter-

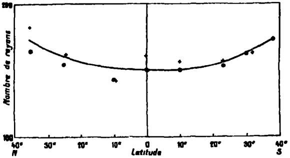

FIG. 1.

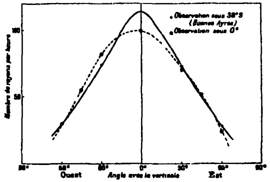

FIG. 2.

position entre les compteurs d'écrans absorbants (20 cm. de plomb) nous ont donné des nombres régulièrement inférieurs de 30 pour cent à ceux obtenus sans écran, la proportion relative de rayons très pénétrants restant donc sensiblement la même (au point de vue des rayons verticaux) sous toutes les latitudes explorées.

Nous avons également étudié la répartition angulaire des corpuscules cosmiques sous différentes latitudes, et trouvé que la symétrie entre les directions est et ouest que l'on observe sous les latitudes supérieures à 30° est détruite au voisinage de l'équateur en faveur des rayons venant de l'ouest, résultat qui est à rapprocher de ceux de Johnson.

La forme de la courbe est également assez différente, comme le montre le diagramme (Fig. 2), dans lequel sont portés les nombres de rayons arrivant sous différents angles à l'est et à l'ouest de la verticale.

La mission était subventionnée par la Caisse des Recherches Scientifiques. Nous désirons remercier la Compagnie des Chargeurs Réunis et l'équipage du vapeur *Kerguelen* qui ont beaucoup facilité notre tâche

Chemical Separation of Diplogen from Hydrogen

WE may reasonably anticipate that in those reactions which proceed at low temperatures, that is, reactions for which the energies of activation are small enough to render them sensitive to the difference in the zero point energies, diplogen and hydrogen will undergo reaction at different rates

We have found such a difference in the velocity of the liberation of hydrogen effected by the solution of metals in water or acids, for the liberated hydrogen does not possess an [H]/[D] ratio ([D] signifies the concentration of diplogen or the heavy hydrogen isotope) identical with that of the original water or acid. For example, on solution of zinc in 0·1 *N* sulphuric acid which contains 25 per cent D ([H]/[D] = 3), the hydrogen liberated contains only 8 per cent of D ([H]/[D] = 11·5), that is, the rates of production of H and D are in the ratio of about 4 . 1[1]. On solution of other metals similar differences are obtained, the approximate ratios for aluminium, calcium and sodium being 2, 1·5 and 1·2 respectively Analogous reactions in which compounds containing hydrogen, such as ammonia, acetylene, etc., are liberated instead of hydrogen, are now being investigated.

It appears possible that a reaction of this type, in which an enrichment of the heavy hydrogen isotope takes place as in the process of electrolysis, may serve as an alternative method for the production of heavy hydrogen and its compounds.

Measurement of the Frequency of Longitudinal Vibration of Non-Magnetic Rods

IT has been known for many years[1] that the resistance of a copper wire is increased by loading and that this increase of resistance is in excess of that which can be accounted for by the accompanying change of cross section. It seemed to be probable, therefore, that this phenomenon could be applied to the measurement of the frequency of longitudinal vibration of non-magnetic rods, since the method which has been described previously[2] cannot be used for such rods.

In order to test this possibility, a rod of the material was suspended in a long solenoid and clamped at the upper end A load was fixed at the lower end and the rod was connected in series with the solenoid winding, which was excited from a 30 volt battery of accumulators. Surrounding the rod near the central part of the solenoid was a search coil of about 20,000 turns, and this coil was connected through a valve amplifier to an oscillograph. The rod was then set in a state of longitudinal vibration by means of a slight tap on the lower clamp. In consequence of the corresponding variations of stress in the rod the resistance changed and the current in the solenoid varied accordingly. These variations of the exciting current induced corresponding E.M.F.'s in the search coil and the vibrations of the rod are thus recorded on the oscillogram The effect is small but definite and the results for two different rods are shown in Fig 1 *a* and *b*

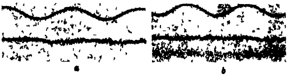

FIG 1

Fig 1*a* refers to a brass wire $\frac{1}{8}$ in diameter, the density being 8·4 and the free length 178 cm. The fundamental frequency of the vibrations as found from the oscillogram is 1030 cycles per second. For a rod clamped at both ends, the frequency *f* is related to the length *l* cm, the density ρ, and Young's modulus *E* by the expression

$$f = \frac{1}{2l}\sqrt{E/\rho} \text{ or, } E = f^2(2l)^2\rho \text{ dynes per sq. cm ,}$$

from which it is found that the value of *E* for a brass wire is 11·2 × 10^{11} dynes per sq. cm , or 16·3 × 10^6 lb. per sq. inch.

Fig. 1*b* refers to a rod of duralumin $\frac{1}{4}$ in diameter, the free length being 209 cm and the density 2·8. The fundamental frequency of longitudinal vibrations as found from the oscillogram is 1180 cycles per second, from which it follows that the value of *E* for a rod of duralumin is 6·8 × 10^{11} dynes per sq. cm., or 9·9 × 10^6 lb. per sq. inch

This investigation is being continued with the view of obtaining a larger amplitude for the wave due to the longitudinal vibrations. A higher frequency for the time calibration wave is also being used.

Polarised Photoluminescence of Adsorbed Molecules of Dyes

I HAVE investigated the degree of polarisation of fluorescence and phosphorescence from 'Cellophane' films coloured by Kautsky's method[1] ('Cellophane' phosphors) The molecules of the dye, adsorbed on the surface of the microcrystals of the film, cannot rotate; therefore the luminescence cannot be depolarised by rotation

The films used, 0·09 mm in thickness, are optically anisotropic It is known that the orientations of the axis of the microcrystals are regular to a certain extent The observations were made with a Savart analyser and a set of compensating glass plates approximately in the direction of the exciting light, perpendicular to the surface of the 'Cellophane' phosphor. The latter could be rotated around this direction and the azimuth (α) could be read The analyser gave the value of $P = (I_1 - I_2)/(I_1 + I_2)$, where I_1 and I_2 are the intensity of the components the vibrations of which are parallel and perpendicular respectively to the direction of the vibrations of the exciting light transmitted through the polariser. When natural light was used for excitation, the same position of analyser was used

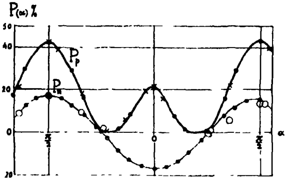

FIG 1 P as a function of azimuth (α) for euchrysine-'Cellophane'-phosphor
P_p, excitation with polarised light.
P_n, excitation with natural light
x and o observed values, ⊗ and ⊖ calculated values from the formulæ

$$P_p = \frac{(\epsilon_1^2 \cos^2 \alpha - \epsilon_2^2 \sin^2 \alpha) \cos 2\alpha - \cos^2 2\alpha}{\epsilon_1^2 \cos^2 \alpha + \epsilon_2^2 \sin^2 \alpha + 1} \quad \text{and}$$

$$P_n = \frac{(\epsilon_1^2 - \epsilon_2^2) \cos 2\alpha}{\epsilon_1^2 + \epsilon_2^2 + 2}$$

Fig 1 shows the $P(\alpha)$ curves for the fluorescence of a euchrysine 'Cellophane'-phosphor, for natural and polarised exciting light In the latter case, it is clear that the degree of polarisation for $\alpha = \pi/2$ is higher than for $\alpha = 0$ For those two azimuths, the exciting light vibrates to one or to the other principal direction of vibration in the 'Cellophane' film. Also when excited with natural light, the fluorescence shows partial polarisation in a certain direction (Fig 1, P_n)

Similar curves were obtained for phosphorescence but the values of $P(\alpha)$ were somewhat smaller.

Anisotropy was also examined by absorption, the absorption coefficients show an anisotropy, however. The position of the absorption band does not depend upon the direction of light vibration.

Although different dyes have $P(\alpha)$ curves of the same character, the values of $P(\alpha)$ differ very much. This indicates that the phenomena are not only due to the anisotropy of the field intensity of the exciting light (caused by the birefringence of the medium) but also to the polarisability tensor of the dye molecules and anisotropy of the distribution of the directions of their axes.

Details of this investigation will be shortly published elsewhere

Predissociation in the Upper Level of the Ångström Bands of Carbon Monoxide

IN taking a photometer curve of the 0 → 1 band $^1\Sigma \rightarrow {}^1\Pi$ ($\lambda = 4835$), we observed that in all three branches, P, Q and R, beginning with the same value $J = 38$ of the upper level, the lines abruptly decrease in intensity to less than half the original value. It seems to us reasonable to assume that this remarkable feature is caused by a predissociation of $^1\Sigma$ into the triplet dissociation term ^3P (oxygen) $+ {}^1D$ (carbon)

Triplet-singlet intercombinations in the emission spectrum of CO have already been observed by Cameron. In this case the selection rule forbidding singlet-triplet transitions does not hold, but at any rate the Cameron bands are much more difficult to get than most of the other CO-bands, even though no other transition to a lower state of the molecule does exist. In the same way a predissociation of a singlet by a triplet term may occur As the transition to the dissociated molecule must be rather improbable, it seems that the life time of predissociation here becomes of the same order of magnitude as that which belongs to a transition with radiation In this case the emission lines do not disappear, but only decrease in intensity as has been observed A triplet-singlet intercombination with predissociation has also been observed by Herzberg[1] in the case of P_2 But for this much heavier element the probability of the triplet-singlet intercombination is already so large, that for P_2 the band lines totally disappear.

From the energy of the predissociation we were able to calculate the dissociation energy of the normal state We found $D = 9{\cdot}82$ volts, in good agreement with the value generally assumed (10 volts). For the other molecular terms we found as dissociation energies $A\ {}^1\Pi$, 1·82 volts; $B\ {}^1\Sigma$, 2·28 volts; $a\ {}^3\Pi$, 3·84 volts; $a'\ {}^3\Sigma$, 3·94 volts; $d\ {}^3\Pi$, 3·10 volts.

The upper zero vibration level of the Herzberg bands lies about 3100 cm.$^{-1}$ *higher* than the dissociation term $^3P + {}^1D$ Thus these bands from their beginning already suffer from predissociation and it is easy to understand why they are much more difficult to get than the Ångström bands.

Further particulars will be given shortly in the new Dutch periodical *Physica*

Effect of Pressure on High Terms of Alkaline Spectra

IN the alkaline spectra, very long absorption series have been observed. Wood and Fortrat have detected 56 terms of the Na, $3S-nP$ series. One might expect that the high terms of the series would be destroyed by adding a foreign gas, as the excited states of high quantum number have such a large volume that the number of molecules of the foreign gas contained in it can be, under experimental conditions, of the order of 10,000.

This argument proves to be untrue, as we have been able to observe the absorption series up to very high terms in sodium-nitrogen and sodium hydrogen mixtures with a pressure of the perturbing gas of the order of magnitude of an atmosphere.

With nitrogen as foreign gas, only a little broadening of the high terms, but no shift, was observed. Instead, in the case of hydrogen, all the high terms of the series are shifted by an approximately constant amount towards the violet. With a concentration of about $4 \cdot 8 \times 10^{19}$ molecules per c.c. of hydrogen, we observed a displacement of $7 \cdot 5$ cm^{-1} as is shown in Fig. 1. This shift is approximately proportional to the concentration of the perturbing gas.

One might attempt to explain this shift with the aid of the ordinary perturbation theory, considering some average potential for the electron over the very many potential holes, representing the foreign molecules contained inside the electronic eigenfunction. This would give a lowering of the high terms, and therefore a shift of the lines towards the red. However, Prof. Fermi has pointed out that this simple theory cannot be applied, as the first approximation of the perturbation theory is not sufficient for describing the phenomenon. His theory shows that the effect, though having the same order of magnitude as elementary theory, can be also of opposite sign, and explain a shift towards the violet as observed for hydrogen. The magnitude of the effect is connected with the limiting cross section of the perturbing molecules in the Ramsauer effect for zero velocity; the theory can also explain the fact that the high terms are not completely destroyed by the perturbation.

FIG. 1. Absorption spectra of sodium-hydrogen mixtures at higher pressures (above) and at lower pressures (below) of hydrogen. Note the unshifted mercury line 2537, which lies in the background.

An account of experiments with different gases and absorbing vapours will be published elsewhere.

Graphical Determination of Contemporaries

LET points representing the years of birth and death of each of a group of individuals—for example, eminent men of science—be plotted with the year of birth as abscissa and the year of death as ordinate on the same scale. Each of these 'life-points' lies above the line $y=x$ since $y>x$, and, if 100 be taken for the limit of age, below the parallel $y=x+100$.

The dotted lines in Fig. 1 show two positions of a 45° set-square of transparent celluloid the hypotenuse of which slides along a straight-edge (not shown) parallel to $y=x$ and at such a distance from it that the apex is always on this line.

At the date given by the position of the apex on the line $y=x$, which may be called the time-line, any individual is not yet born if his life-point is to the right of the vertical edge, and dead if it is below the horizontal edge, while contemporaries are those whose life-points can be seen through the transparent set-square. The ages of these at the date are given by the distances of the points from the vertical edge, and also the ages at death of any of the group are given by the vertical distances of their life-points above the time-line, so that the life-points of all attaining the same age lie on a line parallel to it.

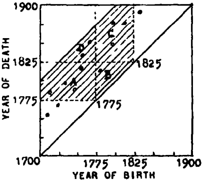

FIG. 1.

Suppose, as an example, that the group consists of thirteen individuals, all of whom are born and die between 1700 and 1900, and that their life-points are plotted as in Fig. 1. Then, placing the set-square with its apex at say 1775 on the time-line (the dotted lines show its position), it is seen at a glance that at this date two are dead, six contemporary, and five unborn. Similarly, at date 1825 seven are dead, five contemporary, and one unborn.

All whose life points are within the shaded area have lived at some time during the period 1775–1825. This area is composed of the parts A, B, C, D. Those with life-points in A were born before and died during the period, in B were born and died in the period, in C were born in and died after the period, and in D were born before and died after the period. When the period is sufficiently long the area D vanishes, and in such case none can be born before and die after the period.

When the number in the group is large the plotting of the life-points is laborious; but, this being done, complete information for any dates and any period can be obtained at once by mere inspection.

Parasitic Infection of Porcupine Fish

BETWEEN the first week in October and the middle of November last, thousands of dead porcupine fish, *Diodon maculatus*, were cast up on the south and west coasts of Ceylon. These dead fish were observed near Galle early in October; by the second week in November they were to be found in large numbers along a stretch of about two hundred miles of sea-coast from Hambantota to Chilaw. The fact that they were first found on the shores of the south-west corner of the island and later along the western coast seems to point to their having been brought in from the deeper waters to the south of the Gulf of Manaar, as their distribution corresponds with the prevailing direction of currents in October and in November

I examined a few of these fish collected at random. All of them were adults of about the same size and all were infested with a parasitic copepod which may be *Pennella sagitta*, the common parasite of *Diodon*. I cannot be definite with regard to this identification on account of lack of literature here and as this copepod differs in some respects from the description of *Pennella sagitta* taken from an *Antennarius marmoratus*[1]—the only description available. Some of the fish had but a single parasite, while others carried two or even three of them In addition, some had chalimus stages of a *Caligus* sp on them.

The cause of the death of this fish in such large numbers is difficult to ascertain Sudden alterations in the conditions of its habitat due to submarine disturbances can scarcely explain it Such disturbances would, no doubt, have affected other organisms living in the same habitat, but of this there has been no evidence whatever Could a plague of this *Pennella* have caused the destruction of such a multitude of these fish? *P. sagitta* is known as a parasite of several species of *Diodon* and *Antennarius* and the presence of one or two individuals does not, in ordinary circumstances, bring about the immediate death of the host Many of them on the same fish would endanger its life, but in this instance they were not present in such numbers as to justify the conclusion that they were solely responsible for this slaughter.

Blood Composition in Relation to Milk Secretion

MANY attempts have been made to determine the changes in composition of the blood that occur in its passage through the mammary gland, with the view of elucidating the mode of secretion of milk. Earlier workers in the field (Meigs[1] 1922) thought that by examining blood taken from the jugular vein they were studying a fluid of similar composition to arterial blood, and undoubtedly the former can be obtained far more easily than the latter in the case of the bovine More recently, Blackwood and Stirling[2] (1932) have suggested that jugular venous blood is more concentrated than arterial, and they attribute this concentration to removal of water by the salivary glands.

Considering the small magnitude of the differences in blood composition which are under investigation in these studies, we feel that attention should be directed to the numerous grave sources of error which may be involved in obtaining blood samples, as in no instance reported in the literature have all of these been taken into account. These errors are fully discussed by Peters and Van Slyke[3] (1931) and the following examples need only to be mentioned, namely, changes in plasma concentration arising from venous stasis, such as may result from compression of the vein, use of oxalate as anticoagulant, undue exercise on the part of the animal or loss of carbon dioxide from the blood sample. In regard to the first point, we have observed such evidence of stasis as œdema in taking jugular samples, and it is a common practice to use means of compression in this procedure We are attempting to eliminate these sources of error from the work we have in progress, and hope to publish more detailed findings in the near future

Catalytic Hydrogen Replacement and the Nature of Over-voltage

DR. J. A V. BUTLER has criticised our remark that the influence of the composition of the liquid phase on the catalysed reaction of hydrogen and water seems to prove that the rate-determining factor is the ionisation of the adsorbed hydrogen and not the preliminary dissociation of hydrogen into adsorbed atoms[1] Butler suggests that changes of the catalyst such as coagulation, may explain our observations Our communication as it stands is certainly open to this objection. We should have added, that in our experiment the greatest care has been taken to meet it, by ascertaining that all changes caused by the composition of the liquid phase are completely reversible. Twenty measurements were made on an identical sample of platinum black, all consistent with one another. Our platinum black was a quickly settling powder, it was shaken 15–20 times per second with an amplitude of 4–5 cm.

In these circumstances a structural change of the platinum black appeared to be an improbable explanation for which we could find no foundation in colloid chemistry. Our recent observations on the activation energy of the reaction, which will be soon reported, have confirmed our assumption.

Research Items

Acaxee of Ancient Mexico. The culture of a forgotten people of ancient Mexico, the Acaxee, is reconstructed from early records by Mr. Ralph L. Beals in *Ibero-Americana*, 6. The Acaxee, although now almost unknown to American ethnologists, once occupied a considerable area in the Mexican Sierra Madre, and remnants are said still to exist. Their culture presents many features unusual in North America. The term Acaxee is applied to a group of languages of the Uto-Aztecan linguistic stock, belonging to the Sonoran and not to the Mexicano-Nahua group. The Acaxee proper had their centre about the valleys of the San Andres and Topia. They differed from the lowland peoples in having a shorter stature and a yellowish-brown complexion. The Spaniards found them an admirable people, except for their persistent head-hunting and their extensive cannibalism. They were agriculturists and the chief features in their culture were warfare, head-hunting and the accompanying cannibalism, games, principally the footrace and the ball-game, and a strong agricultural-religious complex. It is possible that they lived in localised clan groups. It may be that their culture represents an intermediate link between, say, southern Mexico and the southern United States; but more probably it is the culture of a more or less stagnant area, a backwash surviving as a distorted reproduction of an earlier period in the history of Mexican culture.

Sunlight and Death of Snakes. Several notices have appeared in *Copeia* quoting well authenticated reports that rattlesnakes (*Crotalus confluentus*) are killed by short periods (about 10 minutes) of exposure to direct sunlight, and popular belief attributes similar susceptibility to the sidewinder (*Crotalus cerastes*). As a consequence, several observers have tested the reaction of snakes to sunlight with a variety of species, and the general result has been that, in full sunlight on sandy ground, the desert snakes have rapidly become uncomfortable, lost the power of co-ordinating movements and have died in 6–20 minutes. To discover the lethal factor, H. F. Blum and C. R. Spealman tested the light rays and came to the conclusion that no definite part of the spectrum was injurious to the rattlesnake, but that death was due to rise in body temperature owing to the combined effect of the absorption of solar radiation and conduction of heat from the ground surface (*Copeia*, 1933, p. 150). That this supposition came near the truth was shown by testing the reactions of snakes in a hot-air bath. Death resulted when the bath had reached a temperature of 49° C. It is significant that Walter Mosauer and E. L. Lazier found that in all the specimens they tested the body temperature at death was almost identical and was 46·5–47° C. (*Copeia*, 1933, p. 149).

Indian Polychætes. Prof. P. Fauvel has recently given a systematic account of the Polychæta of the Indian Museum, Calcutta (*Mem. Ind. Mus.*, 12; 1932); 306 species, belonging to 30 families, are recorded. The coastal region is, as might be expected, much richer in species than the deep sea, and among the examples from brackish water, modified and often peculiar forms are plentiful; one of them cannot apparently be referred to any known family. As is usual in tropical seas, the families best represented are the Aphroditidæ, Nereidæ and Eunicidæ. Twenty-eight new species are described. This polychæte fauna does not differ materially from that of the Red Sea, the Persian Gulf, the Philippines and the Malay region; many species from the Pacific and the Australian region are also found in the Indian area. Of the 306 species, 67 are also European and the author points out that it is becoming more fully recognised that many polychætes are really cosmopolitan. *Mercierella enigmatica*, first recorded from brackish waters near Caen and from the London docks, was believed to be an exotic polychæte brought home on the hulls of ships. In the collection now described, specimens of *Mercierella* were found adhering to oyster shells from the Ennur backwater, Madras, thus confirming the suspicion of its Indian origin. It was probably brought to London on ships' hulls and transported thence by coasting vessels to the French ports and estuaries from which it has been recorded.

The Frog's Tongue. As the result of a study of the tongue of *Rana hexadactyla*, C. P. Gnanamuthu (*Rec. Ind. Mus.*, 35; 1933) concludes that the movements of the frog's tongue are brought about entirely by muscles; Hartog's view, that extension of the tongue is due to lymph pressure, is untenable. He states that the submaxillaris muscle and the lymph spaces below the hyoid are not adapted to participate in the projection of the tongue. The tongue has two muscles—the hyoglossus and the genioglossus. The hyoglossus remains in a contracted or tonic state when the tongue is at rest and is relaxed when the tongue is pushed out of the mouth. The genioglossus, by which the front part of the tongue is attached to the symphysis of the lower jaw, is peculiarly modified; its dorsal part serves to reduce the length and breadth of the tongue while the ventral or basal part serves to give the anterior part of the tongue a forward pivotal movement.

Aerial and Soil Roots in *Acanthus* and Propagation from its Leaf. A. McMartin has recently published two papers (*Trans. and Proc. Bot. Soc. Edin.*, 31, Part 2, 1933), which deal mainly with the anatomy of the root system. He shows that the differences between air and soil roots must be traced in the main to factors at work in the growth of the apex. In the soil, growth in length is greater than in the air, but in the latter case there is more radial growth and, as a consequence, considerable development of a pith. The aerial roots in this genus have usually been described as 'prop' roots, but their mechanical structure is shown to have little relation to such a function and their presence is correlated with the inadequate radial growth proceeding in the stem, basipetal growth activity taking instead this form of aerial root development, which provides a further source of water supply to the leafy shoot. A second paper describes the origin of the root in leaf cuttings of *Acanthus* and the modification in structure of this root which follows as its proximal end tuberises and then develops buds. An analogy is drawn between the change in structure in this region and in the hypocotyl of the normal seedling.

Mosaic Disease of Raspberries. Mr. R. V. Harris has recently published the results of his investigations on the mosaic disease of raspberries ("Mosaic Disease of the Raspberry in Great Britain. I: Symptoms and Varietal Susceptibility". *J. Pomol and Hort. Sci*, 11, No 3, 237–255, Sept. 1933). The range of leaf symptoms is classified according to severity, as 'type a', 'type b' and 'type c', and the disease seems to be quite distinct from leaf-curl and from a peculiar chlorosis upon the variety Devon. A tentative classification of varieties according to their relative susceptibility is given, and evidence is collected to show that this virus disease becomes worse in certain districts.

Lower Gwanda Gold Belt. The geology of the Lower Gwanda Gold Belt, one of the lesser known inliers of the Basement Schists of Rhodesia, is described by Mr A E Phaup in Bulletin 24 of the Geological Survey of Southern Rhodesia (Salisbury, 1933, pp 74, with coloured geological map). The region is situated about 85 miles south of Bulawayo. As in some of the other gold belts, the Basement Schists are predominantly a series of metamorphosed basic lavas, some of which were limburgites, which must have reached an immense thickness, whatever allowance be made for folding. Sedimentary rocks, including banded ironstone, form only a small part of the lower division of the Series. Proof is given of two periods of granite intrusion and the mineralisation of the gold reefs is referred to the earlier granite. Up to the present, eight small gold mines have been productive, the chief being the Legion Mine, which has produced more than 22,000 oz. of gold. After pre-Cambrian times, denudation removed several miles of rock, before the injection of an easterly swarm of basaltic dykes, probably during late Karroo times. Since then only a few hundred feet of rock have been worn away to produce the present topography.

Climatology in Rhodesia and East Africa. One of the five sections into which the last of the five volumes of Köppen and Geiger's "Handbuch der Klimatologie" is subdivided is devoted to the climate of Rhodesia, Nyasaland and Portuguese East Africa. This section, which has recently been completed, can be obtained, like the other sections, as a separate publication (Berlin: Gebruder Borntraeger. 6 marks) in English. The authors are C L Robertson, chief engineer, Irrigation Division, and N. P Sellick, meteorologist, of Salisbury, Southern Rhodesia. Before proceeding to the general and detailed descriptions of the climates of these countries a short history of their meteorological services is given. From this can be gathered an idea of the difficulties encountered in dealing climatologically with these areas, arising from the fact that until recent times there has been little co-ordination of the observations made by private individuals, on which a detailed knowledge of climate, and especially of rainfall, ultimately depends. There is nothing in this work calling for special notice, the handling of the available statistics being on orthodox lines. Attention is directed at an early stage to the great influence on the weather exerted by the high altitude—3,000 feet or more—of a large proportion of South Africa. The lofty plateau profoundly modifies the movements of the high and low pressure systems appropriate to these low latitudes, and this has, of course, large meteorological consequences; moreover, the influence on temperature of the mere elevation underlies all the seasonal and casual variations of the weather, and mitigates the unpleasantness of some of the climatic features.

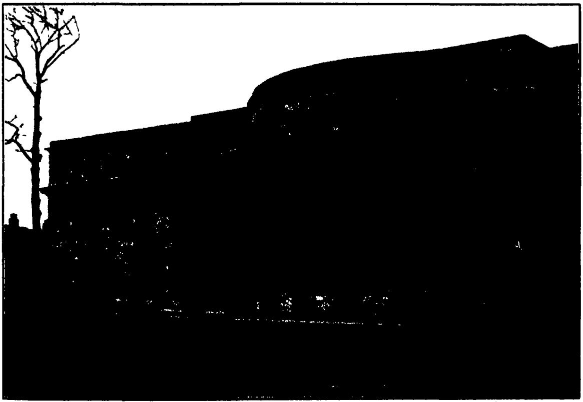
Cold Emission from Liquid Mercury. It has been established that electrons may be pulled out of metal surfaces by a sufficiently large electric field. The quantitative study of this effect is hampered by the uncertainty in the field due to minute roughness of the metal surface. Beams (*Phys. Rev*, Nov. 15) has attempted to study the emission from a liquid mercury surface, which must be free from such roughness. An added interest is in the probable part played by auto-electronic emission in the cathode spot of the mercury arc. In the experiments the mercury pool was cooled by a freezing mixture to keep down the vapour pressure, and an impulsive potential was applied to a spherical steel anode placed just above the mercury surface. Since the potential was applied only for a few microseconds, the mercury surface was not distorted by the electrostatic forces. A rotating mirror photograph shows that the luminous discharge starts at the anode, presumably as a result of bombardment by the electrons drawn from the cathode. The experiments showed that with a clean mercury surface the discharge was initiated by a well-defined field of about $1\cdot8 \times 10^6$ volts per cm. This value is much lower than predicted by the theory of Fowler and Nordheim. Taking the work function of liquid mercury derived from photoelectric experiments (4·53 volts) the theory predicts a field current of less than one electron per second, which could not possibly start a discharge. This discrepancy may be due to the submicroscopic structure of the surface—the author is going to undertake measurements of the photoelectric threshold and autoelectric breakdown at the same mercury surfaces. The magnitude of the autoelectronic threshold indicates that this electron emission may be important in the mercury arc.

Effects of Sun on Radio Transmission. By sending radio impulses to the outer regions of the earth's atmosphere, far above the stratosphere and unreachable by balloons or aeroplanes, physicists have obtained evidence that regular variations in radio echoes are due to the effect of ultra-violet light from the sun. Irregularities in the radio echoes show, however, that they are affected by other causes. In a paper read on December 22 to the American Physical Society, Drs. H R. Mimno and P H. Wang, of Harvard University, discussed the results obtained by using automatic apparatus for 6,000 hours last year. According to Science Service, they pointed out that changes in the electric conductivity of the ionosphere, which extends far above the stratosphere, affect our daily life. Most auroral displays occur at great heights and are accompanied by violent magnetic storms which interfere with telegraph and cable communication. Less violent disturbances may have the effect either of improving or of interrupting radio reception. Long distance trans-oceanic radio communication would not be possible if these atmospheric electric charges were not dense enough to deviate the radio wave and turn it back towards the ground. Even at short distances 'reflected waves' produce 'fading' in broadcast reception, 'ghost images' in television and are responsible for the slow alterations in signal strength noticed after nightfall. Radio transmission is affected by the 11-year sunspot cycle. Substantial progress has been made by physicists in finding out the nature and cause of these continual changes by using radio apparatus merely as a tool in their measurements.

New Chemistry Building of the University of Leeds

SIR FREDERICK GOWLAND HOPKINS formally opened the new building for the Department of Chemistry at the University of Leeds on January 12 (see NATURE, Jan 20, p 95)

The major portion of the new building consists of two wings extending at right angles to the frontage in Woodhouse Lane The shorter or north wing, with its large semi-circular window and pillars of Portland stone, forms a conspicuous external feature, it contains the lecture rooms, large-scale laboratory, workshop, private rooms for the staff, common room, library, and a number of small research laboratories The south wing, which is built of red brick and is not visible from the main road, contains the large teaching laboratories with their service rooms and store rooms. The front section, which faces east on to Woodhouse Lane and connects the north and south wings, contains a number of laboratories for advanced and post-graduate work as well as rooms devoted to the study of special branches of chemistry. The building consists of three floors above ground and a basement extending under the south and east block The ground floor is devoted mainly to inorganic chemistry, organic chemistry occupying the first floor and physical chemistry the second floor All three sections share the lecture rooms, large-scale laboratory, library and the basement, where work requiring freedom from rapid temperature changes and vibration can be carried out. The total floor space in the whole building is about 72,000 sq ft The architects are Messrs. Lanchester and Lodge, of London



Photo] [*Sport and General*

FIG 1 North wing of the new Chemistry Building of the University of Leeds

At the present time the total number of students working in the Department is about 380 undergraduates, including an honours school of approximately fifty, and a research group of from ten to fifteen

The general arrangement of rooms is best considered in relation to the teaching laboratories in the south wing On the ground floor are two inorganic laboratories, each of a floor area of 3,400 sq ft and containing together 144 working places, and a smaller one in the entrance block for more advanced work with 24 places These serve to accommodate the large number of elementary students taking a one year's course, as well as those studying inorganic chemistry as part of a final or special honours subject. The large laboratories each contain twelve bench units of six working places, affording a 5 ft length of space for every student. Each bench unit contains twelve lockers

The gas, water and electrical services run between the girders across the laboratories and are laid under the benches in concrete channels, which also serve to carry the stoneware water pipes from the sinks Accessibility to the channels has been ensured by having the locker cupboards in movable units which can easily be withdrawn. In addition to the usual services, each working place is provided with its own draught flue which fulfils the double function of removing noxious fumes and of ventilating the rooms. The flues, which are constructed of cement asbestos, join up with trunking below the bench level but above the waste channels, and run into ducts of the same material carried in vertical chases in the side walls, to the exhaust fans on the roof of the building. These vertical chases also carry the waste pipes and services and are easy of access for repairs. This principle applies also to all the laboratories in this wing. Situated between the two large laboratories and conveniently arranged are the apparatus store, acid store and steward's office, as well as rooms for furnaces, sulphuretted hydrogen, distilled water, and other necessary adjuncts. In the entrance block, besides the honours laboratory there are a gas analysis room and a balance room, and immediately below the latter in the basement is a small spectroscopic room for teaching purposes.

Research accommodation for the staff of the inorganic section is afforded by a group of small laboratories situated in the north wing. The equipment is simple in character and designed to ensure easy adaptation for carrying out work demanding special apparatus. Ledges with services and movable tables form a special feature of the fittings, and by means of a large duct for services running above the main corridors, it is easy to introduce special types of installation or to modify the existing services (gas, electricity, water or compressed air) as occasion may demand. Amongst this group of rooms is situated the departmental library, containing a valuable collection of chemical journals and treatises from the library of the late A. Chaston Chapman, generously presented to the Department by Mrs. Chaston Chapman in memory of her husband. The basement rooms are also of the same type and designed for post-graduate research. Those under the main entrance are without windows and completely below ground, and have proved to be singularly free from earth tremors and vibration.

The building is heated throughout by radiators supplied with hot water from the University boiler house. Compressed air for laboratories and lecture rooms is supplied from a small compressor in the basement.

On the organic floor the arrangement of teaching laboratories, main stores and accessory rooms is similar but modified to meet the requirements of this branch. Unlike the ground floor, the two large laboratories are provided with island benches, twelve in number, and will accommodate a total of ninety-six students.

Along the east and north wings are distributed five research laboratories for the staff and post-graduate workers, in addition to the professor's private accommodation.

Every laboratory is fully equipped as to services, which include compressed air and direct as well as alternating current. Hooded stone benches for combustions are provided in both teaching and research laboratories, and the space below the fume chambers is utilised for iron-shuttered bomb cupboards. Every island bench has power plugs for stirring motors, and a noteworthy feature is the supply of steam to enamelled iron baths on every working bench in the teaching laboratories as well as to suitable points in the research rooms.

Special attention has been given to the provision of adequate and effective fume chambers. These, both in the research and teaching laboratories, are of large size and lined with Sindanyo material which is specially resistant to the action of organic solvents as well as to acid steam. Gas, water and steam taps can be controlled from outside each chamber. The draught is taken from openings at the top and bottom of the chamber which lead into vertical ducts in the walls to exhaust fans on the roof. The air flow is approximately 500 cubic feet per minute for each chamber. It can thus be claimed that the traditional unpleasantness of organic operations has been largely eliminated. The general lay-out and detailed planning of this floor was mainly the work of Prof. C. K. Ingold, now professor of organic chemistry at University College, London.

The laboratories on the second floor are planned and equipped with a view to the special requirements of teaching and research in physical chemistry. The laboratory benches are to a large extent of the island type without super-structures, and are thus adapted for experimental work with physical apparatus. Particular attention has been given to the electrical services, which provide for the supply of A.C. current from the mains, D.C. current (50–75 volts) from a motor-generator and also constant voltage current from a large storage battery which is connected up with the lecture rooms as well as with all the laboratories on this floor. Extreme variations in temperature have been guarded against by a special form of insulating ceiling.

The accommodation available includes a large general teaching laboratory fitted with fireproof thermostat and side-benches in addition to twelve island benches which provide working places for 48 students. In close proximity to this are, as on the lower floor, a number of smaller accessory rooms—balance room, fume-cupboard room, special apparatus room, store rooms and cloak rooms as well as a drawing office and staff common room.

A special laboratory on the north side is devoted to electrochemistry and experimental work involving the use of heavy currents of electricity. Optical work may be carried out in dark rooms situated partly on the second floor and partly in the basement. Other rooms on the north and east sides of the building are designed for use as special research rooms or for experimental work which cannot be carried out in the main laboratory. The second large laboratory on this floor is set apart to provide for the special needs of medical, dental and pharmaceutical students in physical and organic chemistry.

The lecture theatre accommodation is situated in the north wing, and students have direct access to it without passing through the rest of the building. It consists of two large theatres, seating 250 and 144 respectively, and one much smaller room accommodating 40. The large theatres are specially equipped for experimental lectures; the lecture benches carry all services, and are fitted with draught flues. The natural lighting is from above and can be cut off by a sliding panel operated electrically by the lecturer, who can vary the artificial lighting by a dimmer switch. Special ventilating fans draw in air from behind the heating radiators and exhaust it through the roof, and a wall lining of acoustic board has proved very successful in securing good acoustic properties. The largest theatre occupies the upper part of the semi-circular frontage facing up Woodhouse Lane, and it is noteworthy that no traffic noises are audible inside. The lecture preparation room is conveniently situated between the two large theatres, with a gallery for the manipulation of the diagram screens and a chemical museum on the floor below.

Prize Awards of the Paris Academy of Sciences

AT the annual public meeting of the Academy of Sciences, held on December 11, the prizes and grants awarded in 1933 were announced as follows:

Mathematics.—The Francœur prize to Paul Mentré for his work on geometry.

Mechanics.—A Montyon prize to René Thiry, for his work on the mechanics of fluids; the Poncelet prize to Eugène Bertrand de Fontviolant, for his works on mechanics; the Boileau prize to Adrien Foch, for his works on hydraulics; the Pierson-Perrin prize to Paul Langevin, for his work on the mechanical applications of piezo-electric quartz.

Astronomy.—The Lalande prize to Georges Prévost for his tables of spherical functions and their integrals; the Benjamin Valz prize to Henri Labrouste for his methods of research on periods in solar phenomena; the G. de Pontécoulant prize to David Belorizky, for his work in celestial mechanics; the Antoinette Janssen foundation to Daniel Chalonge for his studies in astronomical physics.

Geography.—The Gay prize to Alphonse Berget, for his treatise on oceanography; the Alexandre Givry prize to the late Pierre Gerson, for his hydrographic work.

Navigation.—The Prix de la Marine between Gaston Dollé and Henri Dutilleul (4,000 francs) for their work on autogenous electric welding and Jean Fieux (2,000 francs) for his applications of the gyroscope to navigation; the Plumey prize between André Grebel (1,500 francs) for his study of combustion in internal combustion motors, the late Paul Leroux (1,500 francs) for his experiments in hydraulics, and Gérard Delanghe (1,000 francs) for his work on Diesel motors.

Physics.—The Gaston Planté prize to Lucien Jumau, for the whole of his work on accumulators; the Hébert prize to Pierre Fleury, for his work on photometric standards; the Henri de Parville prize to Louis Leprince-Ringuet, for his work on atomic physics; the Hughes prize to Salomon Rosenblum, for his work on the α-rays; the Paul Marguerite de la Charlonie prize to Amédée Guillet, for the whole of his scientific work.

Chemistry.—The Montyon prize (Unhealthy Trades) to Georges Darzens, for his work in connexion with the control of petrol storage; Paul Émile Thomas receives an honourable mention for his researches on carbon monoxide and nitrous vapours; the Jecker prize between Mme Pauline Ramart-Lucas (5,000 francs), *for her studies on the relations between the* properties of molecules and their absorption spectra, Émile André (2,500 francs), for his studies on fats, and Raymond Delaby (2,500 francs), for the whole of his work in organic chemistry; the Cahours prize to Georges Allard, for his work on the electronic structure of the ethylene carbon atom and on metallic borides; the Berthelot prize to Henri Moureu, for the whole of his synthetic work in organic chemistry; the Houzeau prize to Paul Laffitte, for his studies on explosives.

Mineralogy and Geology.—The Cuvier prize to Jules Lambert, for the whole of his work on the Echinidæ; the Delesse prize to Christopher Gaudefroy, for his work in physical crystallography; the Victor Raulin prize to Jean Cuvillier, for his work on the Egyptian Nummulitic; the Joseph Labbé prize to Pierre Despujols, for his studies on the mineral resources of Morocco.

Botany.—The Desmazières prize to René Vandendries, for his work on the sexuality of the Basidiomycetes; the Montagne prize to Roger Heim, for his work in mycology; the de Coincy prize to Louis Emberger, for the whole of his work.

Rural Economy.—The Bigot de Morogues prize to Serge Winogradsky, for the whole of his work on the microbiology of the soil.

Anatomy and Zoology.—The Da Gama Machado prize to Jean Verne, for his memoirs on pigments in living beings; the Savigny prize to Georges Sénevet, for his work on the blood sucking arthropods of Algeria and the Mediterranean basin.

Medicine and Surgery.—Montyon prizes to Charles Cot (2,500 francs), for his work on asphyxia, Paul Durand (2,500 francs), for his researches on pustular fever, Jean Lereboullet (2,500 francs), for his memoir on the tumours of the fourth ventricle; honourable mentions (1,500 francs) to J. A. Lièvre, for his book on parathyroidal osteosis, Adolphe Zimmern and J. A. Chavany, for their book on electro-radiological diagnosis and therapeutics of diseases of the nervous system, Henri Velu, for his book on "Dermes"; a citation to Nguyên-Van-Khai, for his memoir on the study of the prophylaxy of cholera by anti-cholera vaccination; the Barbier prize to Augustin Boutaric, for his researches on the properties of colloids and their relations with various biological phenomena; the Bréant prize to Georges Le Dentu, Adolphe Sicé and Marcel Vaucel, for their work on the therapeutics of human trypanosomiasis; the Godard prize to Henry Blanc, for his book on the phenolsulphonephthalein test in urinary surgery; the Mège prize to Edgard Zunz for his book on the elements of general pharmacodynamy; the Bellion prize to Mme. Lucie Randoin, for her work on vitamins; the Baron Larrey prize to Félix Pasteur, for his work on the utilisation of sunlight in the Sahara for the heating and purification of water.

Physiology.—The Montyon prize to Jean Gautrelet, for his book on the elements of physiological technique; the Pourat prize to Jean Chaze, for his biological work on the tobacco alkaloids; the Philipeaux prize to Pierre Dussumier de Fonbrune, for his memoir on a new micromanipulator and arrangement for the manufacture of micro-instruments; the Fanny Emden prize between Herbert H. Jasper (2,000 francs), for his psychological and physiological study of right and left handedness and ambidexterity, and Mme. Andrée Courtois-Drilhon, for her book on biochemical studies on the metamorphosis of the Lepidoptera.

Statistics.—The Montyon prize to Charles Marie, for his work in connexion with the annual tables of constants and numerical data of chemistry, physics, biology and technology.

History and Philosophy of Science.—The Binoux prize to Louis Pasteur-Vallery-Radot, for his work in connexion with the publication of the "Œuvres de Pasteur".

Works of Science.—The Henri de Parville prize to Gustave Juvet for his book on the structure of the new physical theories.

Medals.—Berthelot medals were awarded to Georges Darzens, Mme. Pauline Ramart-Lucas, Raymond Delaby, Henri Moureu and Paul Laffitte.

General Prizes.—The Grand prize of the physical sciences to Clodomir Houard, for the whole of his work, the Bordin prize to Szolem Mandelbrojt, for his memoir on the unicity of Fourier's series, the Lallemand prize to Alexandre Monnier, for his work on the physico chemical mechanism of nerve action; the Petit d'Ormoy prize (Mathematical Sciences) to Arnaud Denjoy, for the whole of his mathematical work and in natural science to Louis Léger, for the whole of his work on theoretical and applied zoology, the Estrade-Delcros prize to Ernest Vessiot, for the whole of his scientific work, the Le Conte prize to Eugène Bataillon, for his work on experimental parthenogenesis, the Parkin prize to René Hazard, for his work on the pharmacology of the alkaloids, the Saintour prize to Georges Giraud, for his work on partial differential equations and integral equations, the Lonchampt prize to Edmond Voisenet, for his work on the production of bitterness in wine and on the Adamkiewicz reaction, the Wilde prize to Mme Irène Joliot Curie and Frédéric Joliot, for their experimental work establishing the existence of neutrons, the Gustave Roux prize to Maurice Collignon, for his palæontological work on the Madagascan fauna, the Charles Dupin prize to Bertrand Gambier, for his work on geometry, the Marquet prize to Alexandre Bigot, for his work on the geology of Normandy

Special Foundations—The Lannelongue foundation to Mmes Gabriel Cusco and Raphaël Ruck

Prizes of the Grandes Ecoles—The Laplace prize to Maurice Allais, the L E Rivot prize to Maurice Allais, Raymond Fischesser, Robert Paoli and Max Dumas

Funds for Scientific Researches—The Gegner foundation to Valerian Agafonoff, for his researches on French soils, the Hirn foundation to Paul Ditisheim, for his work on chronometry, the Henri Becquerel foundation to Ludovic Driencourt, for his work on navigation and geographical maps

Loutreuil Foundation

1 *Researches on Fixed Questions*—Jean Basset (4,000 francs), for researches on the pathogeny and immunisation in anthrax, Charles Lombard (3,000 francs), for experimental researches on the pathogeny of cirrhosis, Pierre Pons (3,500 francs), for researches on wool products from central and southern France, James Basset (5,000 francs), for his studies on the influence of high pressures on physical and chemical phenomena, Jean Dufay and Daniel Chalonge (5,000 francs), for chemical and spectrographic researches on the atmosphere carried out at the Observatories at the Jungfraujoch and at Interlaken; André Charriou, for his researches on the latent photographic image, Paul Henri Fleuret, for his studies of the mechanism of the formation of ketonic and oxalic acids, Laboratoire central d'électricité (12,000 francs), for making the standard of inductance with a view to the measurement in absolute value of the unit of electrical resistance, Charles Marie (3,000 francs), for systematic researches in electrochemistry; Henry Pollet (2,000 francs), for his studies of atmospheric electricity during dust winds in north China

2 *Researches to be carried out in the French Colonies*—Henri Humbert (15,000 francs), as a contribution to the cost of an expedition to Madagascar and southern Africa with a view to the study of various types of vegetation and their variations under the influence of the nature of the soil, altitude and climate; Louis Dubertret (7,000 francs), as a contribution to an exploration of the volcanic desert region to the south-east of Damascus, Jean Piveteau (4,500 francs), to contribute to the cost of excavations in a deposit of vertebrates at Oranais

3 *Purchase of Laboratory Material*—Ecole nationale vétérinaire de Lyon (6,000 francs), for the purchase of a Phillips' portable apparatus for radiography and radioscopy, Léon Huillet (3,000 francs), for the purchase of a Chevenard temperature regulator, Jules Lemoine (2,000 francs), for the purchase of a microphone designed for the study of internal friction in metals, Henri Chaumat (2,000 francs), for the purchase of material for the construction of an electrostatic machine, Maurice Javillier (3,000 francs), for the purchase of an incubator, Raymond Ricard (3,000 francs), for the purchase of a Fabry and Pérot interference standard

4 *Libraries*—The following grants are given to libraries for the purchase of books. Ecole polytechnique (7,000 francs), Ecole national vétérinaire d'Alfort (10,000 francs), Ecole national vétérinaire de Toulouse (2,000 francs), Ecole supérieure de Chimie de Mulhouse (2,000 francs), Société française des Electriciens (1,500 francs), for the purchase of "Faraday's Diary"

Publications—Archives de zoologie expérimentale (10,000 francs), for assisting the publication of a jubilee volume; Bibliothèque national et universitaire de Strasbourg (5,000 francs), as a contribution to the publication of the catalogue of scientific periodicals, Emile Mathias (4,000 francs), for the publication of two memoirs dealing with the action of lightning on man and animals.

Mme. Victor Noury Foundation

Norbert Casteret (2,000 francs), for his hydrological and speleological explorations in the Pyrenees, Mlle Madeleine Friant (2,000 francs), for her book on the dentition of mammals, Josué Hoffet (2,000 francs), for his study of the centre of Indo-China and his ethnological work in Annam, Nicolas Menchikoff (2,000 francs), for his numerous expeditions in the Sahara and the Libyan desert with resulting contributions to geology, Edouard Fischer (1,500 francs), for his researches on the marine fauna of the Channel

Other Foundations

Pierre Lafitte Foundation to René Mesny (3,000 francs), for the whole of his work on radio electricity The Roy-Vaucouloux Foundation to Philippe Lasseur, for his work in the laboratory of microbiology at Nancy. The Charles Frémont Foundation to Léon Pomey (2,500 francs), for his work on geology and analysis.

University and Educational Intelligence

Cambridge.—A lecture on the Liversidge Foundation will be delivered by Prof R H. Fowler in the Lecture Theatre of the Engineering Laboratory on Friday, February 2, at 5 p m. The subject of Prof. Fowler's lecture will be "Heavy Hydrogen"

A LIBERAL education as a prophylactic against the manifold ills that threaten the very existence of western civilisation is the theme of an address delivered at Lehigh University on October 4 by Prof. Hans Zinsser and entitled "None of my Business: or Thoughts of a Biologist on Education" The address is printed in *School and Society* of November 25. The old problem of the relative cultural values of science and the traditional humanities is merged at the present day in another. how to determine the limits of the non-specialist and non-vocational parts of both, for a cultivated man of to day should possess as clear a comprehension of the fundamental laws of science as he does of classical culture and of the language and literature of his own country The great freedom of choice at present allowed in the earlier college years in the United States needs to be curtailed and there should be a far more rigid insistence than at present on a substantial minimum of mathematics distributed between those years and the high school, and general courses in the history of science, in physics, chemistry and biology should be combined with so much of the humanities as is indispensable for intelligent appraisement of the civilisation of our time

THE annual report of the University of Bristol records a small increase in the number of students and several interesting developments in the course of the year 1932–33 A link with New Zealand was established by the foundation of a Hiatt Baker memorial research scholarship of £200 a year tenable for two or three years by a graduate from New Zealand At a celebration of the centenary of the foundation of the medical school, the history of which by Dr G Parker was published without charge to the University by Messrs John Wright and Sons, Lord Dawson of Penn paid a tribute to the work of Prof Fawcett in the faculty of medicine over a period of nearly forty years In co operation with the City Council, the University established a department of preventive medicine which undertakes all the bacteriological, pathological and chemical examinations and research required from time to time by the corporation or its medical officer of health, who is ex-officio professor of preventive medicine A faculty of law was established with the help of contributions from local solicitors and others The university halls of residence were all full throughout the year

THE dispersal of German scholars frowned on in their own land for reasons connected with their political affiliation or racial origin has led to the establishment by the Institute of International Education in New York of a graduate faculty in political and social science comprising Profs Lederer, Brandt, Speier, Wunderlich and von Hornbostel of Berlin, Heimann of Hamburg, Feiler of Königsberg, Colm and Kantorowicz of Kiel and Wertheimer of Frankfort It is hoped that in the near future this faculty will be matched with others so as to form a general "university in exile", a rallying point for distinguished scholars displaced by political intolerance in Europe, and a medium for cross-fertilisation of American and European scholarship For the American student it would perform, by reason of its reproducing the spirit and method of German educational organisation, much the same service as he secured from one or two years of study in a German university. The scheme is described in the Institute's News Bulletin and a summary of it appears in *School and Society* of December 16.

Science News a Century Ago

Insects in the Heads of Mummies

The Rev F W Hope read a paper on January 27, 1834, before the Entomological Society (*J Proc*) in which he described several species of insects found in the heads of Egyptian mummies, some of which had been extracted from the head of a female mummy with plaited hair This was exhibited at the meeting by Mr. Wilkinson, the celebrated Egyptian traveller, by whom it was brought from Thebes. In the head of one mummy was found, it was said, a considerable quantity of the pupæ of dipterous insects . . and from their appearance Mr Hope was led to remark that the process of embalming could not possibly have been a rapid one Mr Pettigrew observed that in some mummies, however, no insects were discovered, as in the one recently opened at the College of Surgeons (see NATURE, Jan 13, p 74)

Currency Problems in the United States

Throughout the year, the United States continued to be agitated by the contest which had begun in the preceding year as to the legality of the conduct of the President in withdrawing the public deposits from the national banks Meanwhile, the importation of gold into the United States went on to an unprecedented extent The increase of specie between the beginning of January 1833 up to June 11, 1834, exceeded 20,000,000 dollars, and the excess of specie imported during the next nineteen days, above what was exported during the same period, came to about 2,000,000 dollars The result of this crisis was that a metallic currency was established for paper money ("Annual Register", 1834)

Drought in England

On the last day of January 1834 a drought began in England and Wales, and from that date until July 4 the rainfall was very limited. At Chiswick the total fall for the whole period amounted to only 4 7 inches, and over England and Wales as a whole the rainfall in the months of February to May inclusive was only 58 per cent of the normal In the early months high temperatures following a wet January caused the vegetation to be very forward, but a series of north-easterly winds and severe frosts in April brought disaster to the fruit crops July was rainy and thundery, but the drought returned in September and was severe in October, November and December. October 1834 appears to have been the driest month of that name in England and Wales between 1810 and 1933 inclusive

Lyell's "Principles of Geology"

In January 1834 the *Gentleman's Magazine* printed the following notice of vol 3 of Lyell's "Principles of Geology" —

"Those who have read the former volumes of Mr. Lyell will have recognised the great alteration and improvement which has taken place in the theory of Geology. The older geologists were more fitted for the island of Laputa than for a Philosophical Society, and even some of the latter were not far behind in pushing forward their crude fragments of discovery With them it was assumed that enormous changes and sudden and violent catastrophes, confounding and dislocating all the globe, were necessary to account for its present aspect Now Mr. Lyell's reasoning goes to the destruction of this ingenious but visionary fabric He considers that the operations *now* going on in the great workshop of nature are sufficient to show how the others that have preceded them have also moved. The changes in animated nature he refers to the circumstances in which the animals are placed Some animals are extinct that were existing a few years ago , others are changed in their nature, habits and climate ; thus, though unmarked except by the thoughtful eye of science, are changes now taking place very similar to those which have so long attracted the wonder and employed the attention of the sons of wisdom. The superentaceous groups form the subject of examination in the third volume Mr. Lyell's account of fossil shells is more extensive and important than ever was given before "

The Post Office

"In my opinion," wrote Lord Brougham, "the teachers of the age of George III covered it with still greater glory than it drew from the statesmen and warriors that ruled its affairs " Brougham himself was one of the first public men to concern himself with national education, and he was the founder of the Society for the Diffusion of Useful Knowledge To this Society was due the publication a century ago of the *Penny Magazine* and the "Penny Encyclopædia", to which many eminent men of science contributed The *Penny Magazine* was issued weekly with a monthly supplement and the supplement for January 1834 was devoted to "The History and Present State of the Post Office" "In the advanced state of civilisation to which we have now attained in this country," the article says, "we possess many advantages of the highest importance which are indeed essential to our daily comfort, but which, presenting themselves with unfailing regularity, pass without observance and almost without our being conscious of enjoying them " Among the principal of them, it was said, may be reckoned an efficient and well regulated system for the transmission of letters *not only in Great Britain but also all over the world* For inland letters the charges were 4*d* for 15 miles, 8*d* for 50 miles, 10*d* for 120 miles and, not exceeding 300 miles, 1*s* 1*d* When a letter weighed an ounce it was charged at four times the rate of a single letter It cost 3*d* to send a letter from Holyhead to Dublin and 6*d* from England to the Isle of Man Charges for overseas letters ranged from 1*s* 2*d* to France, to 2*s* 2*d* to America, 2*s* 10*d* to Gibraltar, 3*s* 2*d* to the Mediterranean and up to 3*s* 6*d* to Brazil Peers and members of parliament could frank ten letters daily The revenue of the Post Office, it was stated, amounted to £97,365 in 1754 , £952,893 in 1804 and £1,457,132 in 1832 The number of persons employed in the post offices of the country in 1829 was 4,905

Richard Lemon Lander

Richard Lemon Lander, the African explorer, died in Fernando Po on February 2 or 7, 1834 There is some doubt as to the actual date, as the accounts vary slightly in detail He was born in 1804 and even as a youth travelled widely, being in the West Indies when only thirteen and he crossed Cape Colony as the servant of Major Colebrook, a commissioner of inquiry, in 1823 With Clapperton, Lander went to West Africa and he brought home the news of Clapperton's death. He published the records of the expedition on his return to England. In 1830 Lander left England in charge of another expedition to the Niger On his return in 1831, he was awarded the first Gold Medal of the then recently formed Royal Geographical Society of London In 1832 a group of Liverpool merchants sent Lander on a new expedition to open up trade in the Niger basin While on this expedition Lander was wounded in an encounter with the natives of the Brass River region and returned to Fernando Po, where he died.

Societies and Academies

LONDON

Royal Society, January 18 B F J. SCHONLAND and H COLLENS · Progressive lightning Eleven lightning flashes, comprising fifty separate strokes from two separate thunderstorms, have been photographed with a rotating lens camera based upon the design of C V Boys The speed was fast enough to permit the study of the propagation of the discharge The majority of the strokes were double and consisted of a dart-like downward-moving leader stroke, followed immediately upon arrival at the ground by a more intense flame-like upward-moving main stroke The mean velocity of the leader strokes was $1\ 1\times10^{9}$ cm /sec along the tortuous track in two dimensions and $7\ 0\times10^{9}$ cm /sec in the vertical direction The dart was less than 54 metres long Corresponding mean velocities for the main strokes were $6\ 0\times10^{9}$ cm /sec and $3\ 8\times10^{9}$ cm /sec The leader strokes are identifiable with electron avalanches and the main strokes with thermally ionised channels The cloud base was negative and the earth positive

A O. RANKINE . A simple method of demonstrating the paramagnetism and diamagnetism of substances in magnetic fields of low intensity The instrument described is the result of an attempt to construct a magnetic gradiometer capable of measuring small distortions of the earth's magnetic field in the same way that the Eötvös torsion balance measures non-uniformities of gravity. Although this purpose has not yet been achieved, the first model of the instrument has revealed itself as a means of demonstrating the paramagnetism or diamagnetism of substances of small susceptibility Moreover, the magnetising fields employed are much smaller than has hitherto been customary, being of the order of 50 gauss or less. The system used also provides a basis for the construction of a new form of very sensitive galvanometer

C W GILBERT The production of showers by cosmic radiation Experiments made with triple coincidence counters showed that the frequency of showers produced in lead by the passage of cosmic radiation is proportional to the general cosmic radiation The transition curves for air to lead were obtained at 3,500 m , and it was found that there the energy of the shower particles was greater than at sea-level To explain the curves obtained, three types of radiation are needed, a primary radiation, a shower-producing radiation and the shower particles

Royal Society of New South Wales, Oct. 4. Adolph Bolliger: Volumetric determination of methylene blue and picric acid. Small amounts of methylene blue and picric acid can be titrated against each other with a high degree of accuracy. The sparingly soluble compound formed, namely, methylene blue picrate, can be readily removed with chloroform, in which it is very soluble. The end point is reached when the watery layer becomes colourless. L. W. O Martin. Quantum numbers and valency. On the basis of London's generalisation of the non-ionic bond and Pauli's exclusion principle, the principal quantum numbers (n, l) of the electron pair bond between two elements are determined It is shown, in the cases examined, that the element of higher atomic number determines the value for n, and therefore that the electron belonging to the atom of lower atomic number must be promoted A connexion between the degree of promotion and the strength of the bond is shown to exist The chemical reactivity is also connected with this promotion

Observations on living Foraminifera show that in many families the occurrence of two or more shells cemented together with the apertures approximately opposed (multiple tests) is the result of the union of two or more individuals for reproductive purposes (plastogamy) with the production of 'zoospores' J L Walsh · An extremal problem in analytic functions. Einar Hille and J D Tamarkin (1) On moment functions (2) On the theory of Laplace integrals. Joseph Miller Thomas. A lower limit for the species of a Pfaffian system Morgan Ward A property of recurring series M H. Johnson, Jr : Intensities in atomic spectra A theoretical discussion leading to the determination of the electric moment with a definite scheme of coupling of the orbital and spin angular momenta, from which the electric moment matrix in intermediate coupling is derived. The components of the latter determine the intensities of the spectral lines. Thomas Wayland Vaughan. The biogeographic relations of the orbitoid Foraminifera Related living Foraminifera are characteristic of shoal water of the tropics and sub tropics, suggesting a similar environment for the orbitoids Since the orbitoids were bottom dwellers, wide geographical distribution requires planktonic larval stages, indirect evidence of which is provided by the observation by Myers of the production of floating 'zoospores' from certain living Foraminifera (see above). Such distribution would probably require a number of sub-oceanic peaks and ridges where there is now deep ocean. Hydrographic and other data suggest that the routes of migration were (*a*) Upper Cretaceous, between Europe and India by way of Tethys and between Europe and America across the Atlantic, (*b*) Eocene, along Tethys, across the Atlantic and from east to west of America, (*c*) Oligocene and most of Miocene, across Central America between the Atlantic and Pacific, thence to the Pacific islands probably to the East Indian region, as well as across the Atlantic and possibly round the southern end of India, but not round the south of Africa.

Industrial Economics

UNTIL 1914, the industries of Great Britain progressed more or less on an even path, developing on conservative lines and only slowly adopting the inventions resulting from scientific research The clash of peoples in the War had a violent repercussion on industry throughout the War, production was pressed to the utmost, there was a free interchange of information, and scientific invention was applied in a hitherto unprecedented manner Post-War trade has experienced first a boom in 1919-20, then a slump lasting until 1925, followed by another and greater boom lasting to the end of 1929, and by an unprecedented depression from which it is beginning slowly to emerge During all these periods, science and invention have been applied to industry as never before, there was money available during the boom periods and need for economy in production costs during the slump

If we take stock to-day, much will be found to have changed, some of our old industries are hard hit almost beyond recovery, newer and more scientific industries have arisen which may be expected to take their place If British industry makes the mistake of attempting to perpetuate the past, the outlook is serious, and apparently it is still foreign to the nature of those who control industry to experiment on the large scale or to act as pioneers of new and untried industries, but fortunately we are proving adept at taking up these newcomers when their teething troubles are past and they have reached the stage of being really practical as well as remunerative, which is more important from a business point of view

Economists have preached from many texts during the depression, at times there have been as many doctrines as preachers—a fact which arises, in our belief, from insufficient knowledge of the practical details of an industry and also perhaps from the inability to grasp the problem as a whole The factors are too numerous to fit into any one theory, their inter-play too obscure to follow easily

Prof Allen, in a most readable book*, has recently attempted to give a picture of the major British industries as they are at present organised After tracing the chief features of industrial development up to 1914, indicating in particular the relative importance of the major trades in the economic life of the nation, he takes several of these trades in turn to describe their rise to prominence, their fortunes during the last decade and their organisation. His selection comprises the staple trades, coal, iron and steel, engineering, shipbuilding, automobiles, and cotton and woollen textiles: it could with advantage have included the chemical and the electrical industries, in which new and progressive methods predominate. He summarises the post-War history and concludes with a chapter on changes in the structure of industry. They are indeed profound, and if the man of science is to go outside his specialised subject, and help the nation at large, he must seek to study them carefully and try to understand their significance.

---

* British Industries and their Organisation By Prof. G C Allen Pp xi+338 (London, New York and Toronto Longmans, Green and Co Ltd, 1933) 10s 6d net

Instability of demand is one of the most difficult problems of modern business. Fashion has a greater and wider influence than ever before, due to the widespread circulation of the newspaper and perhaps also to cheap travel and an accelerated news service. Sir Josiah Stamp has indicated how the increased purchasing power resulting from a fall in the price of boots, due to improved methods of manufacture, may be devoted to the buying of gramophones, so setting up a new industry and providing new employment. But at any moment, the public may leave gramophones for a new interest, for example, radio, and the elaborate and costly plant and organisation built up to supply gramophones fall on evil days. In a sentence, the demand for goods and services satisfying secondary needs is less stable than is the demand for the necessities of life. It is indeed optional and erratic, as witnessed by the fact that one result of the universal adoption of the cigarette-smoking habit by our women-folk has been a diminution in their consumption of chocolates.

A like change has come over the markets for raw materials—in part due to chemical discovery—which is likely to play a continually growing part henceforth. There are enthusiasts who claim that the chemical revolution will bring lower costs, a far wider range of raw materials, a growing multitude of new products and the increasing replacement of familiar wares by superior synthetic articles. Cheaper goods, more goods, new goods, will tend to keep the wheels of industry turning, to make more work, to create new wealth, to distribute purchasing power more broadly. On the other side of the picture, these changes in the sources of raw materials will alter the relative advantages of different countries for specific manufacturing industries.

The change is inevitable, the problem of the transference of national resources to other activities must be faced: the future means more research by a greater number of workers, or perhaps, as Mr. E. W. Rice has said recently in the United States, "the time will come in industry when research will be regarded as more important than advertising". As Prof. Allen rightly emphasises, the economic system has become more rigid. Wage rates are inelastic, oncosts make up a high proportion of the total cost, mass-production technique, standardisation, rationalisation, all have had their effect. It would seem, he says, that technical factors have been given too much weight in determining the organisation of production, whilst widespread national advertising and instalment-selling have accentuated the instability of demand.

The elimination of the small firm by larger corporations with greater resources and apparently also greater bank protection, has eliminated in times of crisis what used to be termed 'healthy bankruptcy'. Output is maintained in times of stress at the bare cost of labour and materials without any contribution to overheads. Such competition is ultimately fatal, not only to the firm but also to the industry, to the nation and to the world—it is equivalent to slow decay. Such a policy is, more than any other reason, in our opinion, the cause of the present world crisis.

There have been great changes also in administrative methods—indeed a new science of industrial management is being evolved which will in time bring order out of chaos. The delegation of authority in a great business is a most important problem—the specialist is replacing the all-rounder. We find planning, employment, costing, purchasing and stores departments all entrusted with specific duties, the work of which has in turn to be co-ordinated.

Another problem is that arising out of joint stock management by experts for shareholders in substitution for that of interested owners. The disappearance of the family business has involved a loss of personal relationships with the workpeople, which can only be regretted. Labour claims a greater voice in industry; much depends on the wise solution of these claims by co-partnership or some other means. Topics of this kind surveyed by Prof. Allen will well repay serious consideration by all who seek to be in touch with the most important of our national problems. We live by industry, not by politics.

E. F. A.

Human Biology and Legalised Sterilisation

THE Report of the Departmental Committee on Sterilisation, which was appointed in 1932 to examine and report on the information available regarding the hereditary transmission and other causes of mental disorder and deficiency, to consider the value of sterilisation as a preventive measure, and to suggest what further inquiries might usefully be undertaken in this connexion, was issued on January 18. The Report is a most valuable summary of modern knowledge relating to an urgent social problem. It surveys the causes and extent of mental disabilities, considers the results of sterilisation, and makes important recommendations for a change in the law and practice in Great Britain. A survey of Dominion and foreign legislation relating to sterilisation is included, so that the Committee's own recommendations can be considered in the light of practice in other parts of the world.

The Committee recommends that voluntary sterilisation should be legalised in the case of a person who is mentally defective or who has suffered from mental disorder; a person who suffers from, or is believed to be a carrier of, a grave physical disability which has been shown to be transmissible; and a person who is believed to be likely to transmit mental disorder or defect. The Committee was, of course, mainly concerned with the question of sterilisation. The constitution of the Committee was such as to make it possible for the Report to include the statement that "we may perhaps be allowed to say that our recommendations are *not* a compromise between conflicting views adopted reluctantly in order to secure the appearance of agreement. On the contrary, we were fortunate at the end of a long enquiry in finding ourselves in complete harmony". This in itself distinguishes this Report from that recently issued by a Committee of the British Medical Association.

The Report expresses the opinion strongly that sterilisation should be voluntary, and insists on stringent medical and administrative safeguards to prevent hasty operations. It urges that the same procedure should apply for physical defects which are known to be inherited. It emphasises the point of view that sterilisation cannot replace institutional treatment, and that even if voluntary sterilisation were adopted on the largest scale, there would still be need for more and not less institutional accommodation than is at present available. Finally, the Report stresses the need for further research in several fields. It points out the striking fact that almost all State-aided research in heredity has been inspired by agricultural needs, and asks whether human heredity is not as important as that of cattle and wheat.

From the volume of adverse criticism even now appearing in the popular Press, it is to be assumed that the Committee's recommendations will meet with great opposition in Parliament and that in all probability they will not gain the support of law. It is improbable that any political party will incorporate these recommendations in its own programme, though this may happen perhaps in ten or twenty years' time. In the meantime, it must be sufficient to rejoice in the fact that it is now becoming officially recognised that man is in charge of his own destiny and that no kind of absolute authority will prevent us from tackling our own problems. The Report possesses a unique interest, for it represents the first attempt in Great Britain to apply pure biology in social practice. It is a scientific document, and its recommendations are in no way coloured by religious or political considerations. It heralds a new era in social legislation.

A Panorama of Geometry

Principles of Geometry. By Prof. H. F. Baker. Vol. 5: *Analytical Principles of the Theory of Curves.* Pp. x+247. (Cambridge: At the University Press, 1933.) 15*s*. net.

IT will be immediately admitted by all mathematicians that the foundations of pure geometry were well and truly laid by the Greeks in the period preceding and succeeding the time of Christ. They investigated in great detail the properties of the straight line, the circle and the conic sections. They had few general principles governing their researches; they were on the outlook for interesting geometrical properties wherever they could find them. On the other hand, Euclid attempted to collect all these scattered theorems and to present them in a coherent whole, studying at the same time so far as he could the underlying postulates and axioms. Nevertheless, it still remains true that the discovery of individual theorems was rather at haphazard.

It fell to Descartes (1596–1650) to devise the geometrical representation of an equation in x and y by means of abscissæ and ordinates. Thus was introduced a general method of attacking any geometrical problem, and furthermore the notion of the 'degree' of a curve obtruded itself It became apparent that the 'straight line' of the ancients was no more and no less than the geometrical representation of an equation of the first degree in x and y Similarly, the conics, including the case of the circle, are merely geometrical representations of equations of the second degree in x and y

Acting on these general ideas, Newton (1642–1727) and Maclaurin (1698–1746) attacked the curve of the third degree (usually called the cubic curve), and made substantial discoveries It was not, however, until the middle of the nineteenth century that any progress could be made with the curve of the fourth degree Its bitangents were discussed by Steiner (1796–1863) and Hesse (1811–1874) The properties of the plane quintic curve have been investigated during the last ten years, but practically nothing is known about the general sextic curve, though a considerable amount of research has been done on particular types of sextics

Simultaneously with these explorations into the properties of plane curves of successive degrees, came investigations into surfaces of the first and second degrees, that is, planes and quadrics The surface of the third degree received detailed treatment at the hands of Steiner, Sylvester (1814–1897), Salmon (1819–1904), Cayley (1821–1895) and others Little is known about the general quartic surface, though much information has been obtained about special types These researches into concrete curves and surfaces of the lower degrees inevitably led to speculations as to the more general characters of curves and surfaces, and particularly those possessing double points and cusps An epoch-making discovery that transformed the whole aspect of geometry was made by Plücker (1801–1868) when he found the exact effect of the possession of double points or cusps upon the number of double tangents, points of inflexion, and tangents from a point that the general undegenerate curve possesses

Another profound influence, though affecting pure geometry less directly than those above mentioned, underlay the discoveries of Abel (1802–1829). By his work on algebraic functions and their Abelian integrals, this young mathematician, caught off in early manhood by tragic death, in the words of Hermite "a laissé aux mathématiciens de quoi travailler pendant cent cinquante ans" The geometrical interpretation of Abel's theorems leads at once to the study of linear systems of points on a curve The possibilities of Abel's work were extended by the work of Jacobi (1804–1851) on the theta functions and of Riemann (1826–1866) on the surfaces that bear his name Jacobi's work on the theta functions leads immediately to the study of contact curves and surfaces There is no textbook which will give a better idea of the general outlook in the middle of last century on geometry as affected by the development of Abel's discoveries than "Theorie der Abelschen Functionen (1866)" by Clebsch (1833–1872) and Gordan (1837–1912) This book in 333 pages develops the theory of the theta functions from first principles, avoiding all general function theory and using only the methods of relatively elementary algebra and geometry Throughout, the book is frankly geometrical in its outlook and even in its notation The student of the history of geometry cannot afford to neglect this work and it will well repay perusal

The general idea of the genus of a curve soon obtruded itself from several quarters There are p Abelian integrals of the first kind A plane algebraic curve which has p double points or cusps less than the maximum number that it may have without degenerating has several characteristic properties Thus a curve of genus (or 'deficiency') zero can have its co-ordinates x, y, z expressed as polynomials of a single parameter t A curve of genus or 'deficiency' one requires the use of elliptic functions for the expression of x, y, z in terms of a single parameter U The reduction of an n-sheeted Riemann surface to one of two sheets with p holes in it presents the same result from still another point of view

These basic ideas gave an impetus to the study of the higher geometry in every direction Space forbids any further preliminary discussion, but it seemed desirable to give the above rough and very incomplete sketch in order that those whose interests are not primarily geometrical should be able to form a competent view of the setting of the field, with which Prof H F Baker's vol 5 of the "Principles of Geometry" is concerned

Prof Baker has placed mathematicians in general and geometers in particular under a very deep obligation for his six volumes on the principles of geometry Their design is to lay before the reader a panorama of the subject and Prof. Baker has achieved his main object extraordinarily well Not only can the general mathematical reader obtain a deep and detailed insight into the development of algebraic geometry, but also the professional geometer will never fail to find something new in these pages. It has been a tremendous task carried out with Tolstoyian vision

Vol 1 deals with "Foundations", vol 2 with "Plane Geometry (conics, circles, non-euclidean geometry)", vol 3 with "Solid Geometry (quadrics, cubic curves in space, cubic surfaces)", vol 4 with "Higher Geometry (being illustrations of the utility of the consideration of Higher Space, especially of *four and five dimensions*)"; vol 5 with the "Analytical Principles of the Theory of Curves", vol 6 with an "Introduction to the Theory of Algebraic Surfaces and Higher Loci". Vol 5 is that immediately under review. It consists of eight chapters dealt with in 247 pages Chap i is an introductory account of rational and elliptic curves, chap ii deals with the elimination of the multiple points of a plane curve; chap iii with the branches of an algebraic curve, the order of a rational function, Abel's theorem, chap iv with the genus of a curve, fundamentals of the theory of linear series, chap v with the periods of algebraic integrals, loops in a plane, Riemann surfaces, chap vi with the various kinds of algebraic integrals, relations among periods; chap vii with the modular expression of rational functions and integrals, chap viii with enumerative properties of curves

The general structure of vol 5 and its place among the other volumes of Prof Baker's series will now be clear He deals in it with the researches of a hundred and thirty years The book is general in character and presents by no means easy reading throughout This is only to be expected where the subject-matter is often so essentially fundamental in character, but the author has very judiciously inserted copiously concrete examples from the case of specific curves and surfaces, and thus the reader's feet are kept on firm rock and he is not allowed to lay down the book with a notion of the treatment of vague generalities The first part of the volume deals with linear series of curves and the sets of points they cut out on the basic curve by the methods of algebraic geometry; the second part presents much of the same subject-matter from the point of view of Abel's integrals and Abel's theorem. The theta functions and contact curves are mentioned but do not receive detailed treatment The Riemann-Roch theorem and its consequences are expounded in great detail.

It only remains to add that vol 5 has been printed with all the finish that one has learned to expect from the mathematical works issued by the Cambridge University Press The treatment itself displays on every page the profundity of learning and mathematical resource that one has long associated with the name of its distinguished author W P M.

Research and the Community

Ideals of a Student By Sir Josiah Stamp Pp 240 (London Ernest Benn, Ltd, 1933) 8*s* 6*d* net

SIR JOSIAH STAMP is known to all as the president of the executive of the LMS Railway, and as a leading authority on the theory and practice of public finance Apparently he has two major forms of relaxation One is the reading of books on all possible subjects, from the Law Reports to the textual criticism of the New Testament, and from seventeenth century books on morals to the latest publications in physics, biology, economics, psychology and philosophy. The other is giving addresses to universities and educational societies, both in Great Britain and in North America, on topics appropriate to these bodies His latest book is a synthesis of these two hobbies It welds together in a continuous argument the themes of perhaps twenty speeches and talks delivered on various occasions during the past few years, and it contains the cream of his reflections upon his 'holiday reading', amply supported with quotations and comments

There is in truth something Aristotelian about Sir Josiah Stamp He has Aristotle's encyclopædic knowledge and Aristotle's philosophically matter of fact approach to the problems of life and learning He has to a great degree Aristotle's literary style—the same series of jerky paragraphs, not always well rounded or carefully coupled with one another, the same love of appropriate, if allusive anecdote, the same readiness to put in the closest juxtaposition discussions of first principles and advice on day to day conduct—in a word, the same sturdy refusal to allow the outpourings of a well-stocked mind to be cramped by the bonds of systematic exposition The argument of his book would have commended itself to his great predecessor For he is concerned with the two main problems which exercised Aristotle when he wrote the *Ethics*—the problem of "theoretical wisdom", or the search for truth, and the problem of "practical wisdom", or the ways in which knowledge can help us in the ordering of our lives

Broadly speaking, the former subject is the theme of Chaps iii, iv, and vii, and the latter of Chaps i, ii, v, and vi Chaps iii and iv discuss the function of universities as institutions for the furthering of knowledge They are remarkable for the understanding which they show of the special problems facing researchers in all the main fields of learning They will be a source of encouragement to those who have feared that doctoral theses, at any rate in literature and the social sciences, are largely a waste of time

Sir Josiah Stamp does not despise even investigations into methods of dish-washing or into the reactions of the young to the emotional stimuli of the 'movies' He is also more sympathetic than most of us towards the desire of the writers of theses to have them published Neither for detailed pieces of work nor for knowledge as a whole does he believe in the overriding necessity for finality , and in Chap vii he urges that since our knowledge of the universe must be incomplete, we need not be too greatly upset if (as in physics at present) we cannot always reconcile it with itself

On the problem of the relation of theoretical knowledge to practical problems Sir Josiah is equally helpful In Chaps i, ii, and vi, he examines the part that must be played by universities and schools of economics in the modern world He sees one of the chief dangers in the present situation in the fact that so many of our political and economic problems require a greater general knowledge and (still more) a higher capacity for weighing evidence and judging impartially, than the average citizen of to-day possesses Universities can put this right if they will both train their students in the technique of research and also provide them with an understanding of the unity of modern problems Chap v, "On Improving all Things", discusses one particular aspect of this subject—the relation of Christian ethics to the problems of capital versus labour, and nationalism versus internationalism This is perhaps the only part of the book in which Sir Josiah's wide sympathies and his ability to see both sides of every question lead to his becoming ineffective, and perhaps doing less than justice to his own convictions It is fairly clear from the rest of his work that he really believes nationalism to be a main source of our economic and political troubles Why, then, does he not say so openly and unequivocally ?

L M FRASER

A Modern Flora

The Flora of Leicestershire and Rutland . a Topographical, Ecological, and Historical Account with Biographies of Former Botanists (1620–1933) By Arthur Reginald Horwood and the late Charles William Francis Noel (Lord Gainsborough) Pp cccxvii+687+36 plates (London Oxford University Press, 1933) 35s net

THIS extensive work comprises about a thousand pages of small print When it is taken into account that Leicestershire is a county rather poor in species, including, as the author states, only about one half of the known British species, it is clear that much of the book is taken up with matter not usually included in a flora The bulk of this matter is in the 300 pages of introduction, which gives chapters not only on the geology, meteorology, soils, agriculture and botanical districts of the region covered, but also on the ecology of the counties, together with a very comprehensive section on the local botanical collections and investigations, with full biographies of those concerned This is indicated by the subtitle In all cases Rutland is dealt with separately.

What may be named the new features of the flora proper consist largely of a meticulous account of first records and the attempt to refer each species to what may be termed its ecological home There will be many botanists, and it is to be hoped field naturalists also, who will agree with Mr. Horwood as to the importance of the geological and ecological factors in their bearing on the occurrence and distribution of the elements of a flora, but many will also feel that it is possible to overweight a flora even in these respects and particularly in matters of biography In any event it may well be thought that the desirability of including ecology in floras is as yet something of a counsel of perfection, in view of the comparative paucity of ecologists and ecological data as compared with collectors and collections. It is greatly to be hoped that one day we may have *ecological* collections, reference to which will probably tend in time to reduce the recorded number of varieties, if not of species

Since as a specialised study and indeed a sub-science ecology belongs almost to the present century, and has arisen entirely during the fifty years since the issue of the previous "Flora of Leicestershire" in 1886, the new "Flora" reflects very well one of the great developments of botanical science which has arisen in the interval.

The authors are to be congratulated therefore on the ecological atmosphere with which they have infused the book They might perhaps also—in view of the generous plan of the work—have included some remarks on the even more important and voluminous edifice built up by the geneticists during this period and its bearing on hybrid species Seventy-two hybrids are reported in the summary furnished by Mr Wade.

The change in the flora itself during the fifty years is shown by the enumeration of 50 species which have become extinct and of others erroneously recorded, on the other hand, one may quote *Pyrola minor*, discovered in 1913, as one of the additions

The 1933 "Flora of Leicestershire and Rutland" is undoubtedly a splendid work of reference, adorned with excellent maps and photographs, incorporating as it does much more scientific information than one had any right to expect of a flora, but possibly a precursor of a new type Nevertheless its issue in two volumes would probably have added to its usefulness

The Committee which has remained in being for twenty years (1912–1933) is to be congratulated on its tenacity and generosity in finally overcoming all difficulties, and, through the labours of Mr Horwood, bringing its work to a successful conclusion E N M T

Short Reviews

Hydraulics By Prof Horace W King and Prof Chester O Wisler Third edition, revised Pp xii+292 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1933) 16*s* 6*d* net

IT is a significant instance of the mutability of word meanings that the term hydraulics, which a generation or more ago was limited to the practical applications of the science of hydrodynamics, distinct alike from that subject in its theoretical aspect (that is, neglecting viscosity) and from hydrostatics, is now very commonly used to denote the whole field of hydromechanics. In an authoritative article by the late Prof. Unwin, in the ninth (1881) edition of the "Encyclopædia Britannica" the distinction just given is clearly drawn On the other hand, in the textbook under notice, as also in other cases, the writers treat hydraulics as an omnibus subject comprising the three divisions of hydrostatics, hydrokinetics and hydrodynamics

It is obvious, of course, that no satisfactory knowledge of the behaviour of water in motion can be acquired without some fundamental acquaintance with its characteristics when at rest, but this is not quite the same thing as making hydraulics a compendium of the physics of water. One disadvantage which presents itself is that the field becomes too wide for effective treatment in brief compass, and the writers of the present exposition cannot claim to have covered the whole of the ground in the book of less than 300 pages.

About one-sixth of the work is devoted to hydrostatics, and roughly the same amount to theoretical hydrokinetics and hydrodynamics The remainder relates to hydraulics in the old sense of the word, and provides a consideration of flow through orifices and tubes, over weirs and dams and in pipes and open channels, including both uniform and non-uniform flow, the latter being a subject of some novelty in textbooks The present issue is the third edition, so that the book has attained a satisfactory measure of acceptance, which is justified by the clarity of treatment, both in regard to the text and the diagrams Students will undoubtedly find it useful as an introductory survey of the subject, more particularly on the theoretical side Each chapter has appended a number of problems to which the answers are given B C.

Riddles of the Gobi Desert By Sven Hedin Translated from the Swedish by Elizabeth Sprigge and Claude Napier Pp x+382+24 plates. (London George Routledge and Sons, Ltd., 1933) 18*s* net

IN this volume, the narrative of the Sino-Swedish expedition to the Gobi Desert, which was at work continuously from 1927 until 1933, carries the story on for a further period of two years It resumes with the author's return journey to Sinkiang from Sweden in 1928, and closes with reports covering the work of exploration up to the end of 1929 As the author was busily engaged in the administrative work of the expedition in China, and was further distracted by a journey to the United States, which was extended to Sweden, on account of his health, he was unable to take the field in person, and his detail is necessarily drawn from the reports of his colleagues His narrative is none the less absorbing and, when he is dealing with the incidents of his own journeys, is vivid in its sketches of persons and events

The closing chapters of the book embody the individual reports of members of the expedition on the different departments of investigation, meteorology, palæontology, geography, archæology, etc. Although of a preliminary character only, they are sufficiently full to indicate the importance of the material obtained Further detail, especially that relating to the neolithic civilisation of the desert and the painted pottery resembling that from Honan, will be awaited with interest A chapter added after the publication of the Swedish edition of the book records the discovery of the new Lop Nor in 1931

Much of the narrative is occupied with the difficulties encountered by the expedition in its relations with Chinese provincial officials At Peking and Nanking, all, from President downward, were most cordial and the whole learned and official world co-operated to promote the success of the expedition in every way

(1) *Intelligence and Intelligence Tests* By Rex Knight (Methuen's Monographs on Philosophy and Psychology) Pp ix+98 (London Methuen and Co , Ltd , 1933) 2*s* 6*d* net

(2) *Psychology and the Choice of a Career* By Dr F M Earle (Methuen's Monographs on Philosophy and Psychology) Pp vii+103 (London Methuen and Co , Ltd , 1933) 2*s* 6*d* net

THE purpose of the series of monographs to which these two books belong is the entirely commendable one of setting forth, for the benefit of the general reader, and with a practical end in view, the results of some of the best recent work in the fields of psychology and philosophy This purpose is well achieved in both of these two members of the series In each case the problem is a very practical one, and in each case the author manages to show, simply but without any sacrifice of accuracy, how scientific method is contributing towards its solution

(1) Mr Rex Knight gives a clear and concise account of intelligence tests, and of their use in diagnosing mental deficiency, in the grading of pupils, in the study of difficult children, and in vocational guidance and selection

(2) In Dr Earle's book the general principles of vocational guidance, so far as they have yet been discovered, are systematically stated In such guidance, as the author shows, not only the psychologist, but also the parent, the doctor, the teacher, and the employment officer, each has a part to play

Both these introductory manuals are fittingly equipped with brief but sufficient advice as to further reading

Textile Electrification · a Treatise on the Application of Electricity in Textile Factories By Dr Wilhelm Stiel Authorized translation by A F Rodger Pp xix+608+6 plates (London . George Routledge and Sons, Ltd , 1933) 63*s* net

THE textile industry has probably gone further than any other industry in replacing handicraft by machine production The transition took place in the first half of the nineteenth century concurrently with the introduction of steam power. This led inevitably to displacing the cottage industry (spinning wheel and hand-loom) by large mills So successful was the use of steam power and line shaft driving that manufacturers were loath to change to electric power and individual drive In the development of individual driving by electric motors, Germany has played the leading part This has opened up new prospects for small textile undertakings. It looks as if it might revive the cottage industry As the English-speaking countries possess more than half the world's cotton spindles, the importance of spinning and weaving to Great Britain justifies the translation of this standard work into English The book is thoroughly practical and can be warmly recommended to everyone connected with the textile industry

Our Forefathers, the Gothonic Nations a Manual of the Ethnography of the Gothic, German, Dutch, Anglo-Saxon, Frisian and Scandinavian Peoples By Dr Gudmund Schutte Vol 2 Pp xvi+483+20 plates (Cambridge . At the University Press, 1933) 30*s* net

IN the second volume of "Our Forefathers", Prof Schutte, having already in his first volume disposed of general questions relating to the Indo-Germanic peoples, passes on to deal with individual 'Gothonic' groups Each is taken in turn and its early history reviewed in the light of the evidence of literary records, philology, place-names, tradition, archæology and ethnology The Anglo-Saxons and the Scandinavian peoples, naturally, receive extended treatment

Prof Schütte has had the advantage of the assistance of specialists, but where this has been unobtainable, his own critical examination of the evidence and his suggestions in dealing with controversial points are both acute and stimulating His book will be invaluable for reference purposes in the study of the early history of the European peoples, pending the production of the detailed ethnology to which he regards his own work as merely preliminary

Phytopathological and Botanical Research Methods By Prof T E Rawlins Pp ix+156 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd., 1933) 15*s* 6*d*. net

THE rapid development of plant pathological investigations, and the increasing use of microchemical methods, have created a need for a survey of the various microscopic and culture methods adopted by workers in these subjects.

Considerable experimental work was done before publication, and many of the methods described are new, while others demonstrate improved technique Though primarily intended for phytopathologists, workers in other fields should find much useful information. A short, but suggestive, chapter is given on the interpretation of experimental results, and an important section of the book is the bibliography, with nearly one thousand references covering a wide field of investigation.

Mendeléeff (1834–1907) and the Periodic Law

DMITRI IVANOWITSCH MENDELÉEFF, who was born on February 7, 1834 (N S) and was for many years professor of chemistry at Leningrad, is chiefly remembered for the first clear and satisfactory enunciation of the Periodic Law, the discovery having been made in the latter part of the year 1868 and announced in 1869 He found that when the chemical elements are set out in an unbroken row in the order of the atomic weights, certain breaks become apparent, and the whole range divides itself into groups of related elements This result, expressed in the law that "the properties of the elements are in periodic dependence on the atomic weights" is the basis of the Periodic System, or Periodic Table In arriving at this conclusion, Mendeléeff was influenced mainly by the previous attempts at classification made by Dumas, Lenssen, Pettenkofer and Kremers, especially the first two, those of Newlands in 1863, and of others, being unknown to him A similar result had been achieved by Lothar Meyer in 1868, but was not published

A German abstract of Mendeléeff's discovery, containing all the essential features, appeared in 1869, in which year it was thus generally known in Europe, and a long paper of 1871 gave a table which is essentially in its modern form These publications attracted very little attention, but the interest of chemists was aroused by the discovery, in 1875 and 1879, respectively, of the elements gallium and scandium, which were found to have the properties predicted for the missing elements which Mendeléeff had called ekaaluminium and ekaboron, places for them being reserved in the table. The element germanium, discovered in 1866, was also recognised as the ekasilicon of Mendeléeff These discoveries made it clear that the Periodic Law was a fundamental truth, and the further progress of research has emphasised more and more its supreme importance in the study of the elements

The discovery of argon was an indication to Ramsay that a new group of elements of zero valency must be added to the table, and the elements helium, neon, krypton and xenon were before long added to the group, and the last member is the radioactive emanation The suggestions of Mendeléeff that this group also contained two other elements, one being the ether, of very small atomic weight, and the other an unknown element of atomic weight less than 0 4, and that there was a missing element of the halogen group, of atomic weight 3, have appeared inconsistent with modern views of the structure of the atomic nucleus.

The regularities among the atomic weights of the elements as disclosed in the Periodic System could not fail to revive speculations about a primary matter, which had attracted chemists since Prout had suggested that this primary matter was hydrogen. Mendeléeff was entirely opposed to this hypothesis of primary matter The difficulty of fractional atomic weights was removed by the discovery that many elements are mixtures of isotopes, and the investigations on atomic structure showed that the Periodic Law is a consequence of the formation of atoms from protons and electrons This recognition of isotopes also removed the objection that some pairs of elements, such as iodine and tellurium, were apparently placed in the wrong order in the table on the basis of their atomic weights, their true positions never being in doubt The discovery that the position of an element in the table is really conditioned by its atomic number, or the positive charge on the atomic nucleus, gave the Periodic Law a fundamental character, and the theory of atomic disintegration enabled all the newly discovered radioactive elements to find their places in the lower part of the table, in many cases a single place containing several isotopes of the same atomic number.

An outstanding difficulty was the position of the elements of the rare earths After lanthanum and cerium came a large number, not definitely known, of elements of very closely related properties, clearly belonging to the same group After these came the element tantalum, obviously in the fifth group For many years the rare earth element cerium, which *forms* very stable compounds in which it is quadrivalent, was considered to be the fourth group element of the rare earths This difficulty was overcome on the basis of the theory of atomic structure by Bohr The pronounced tervalent character of the rare earth elements, preserved with steadily increasing atomic weight, was shown to be a consequence of the presence in their atoms of incompleted inner electron levels, the filling up of which, by successive additions of electrons to keep step with the increasing nuclear charge, left unchanged the outer valency electrons. The atomic numbers of the rare earths were also determined by X-ray spectroscopy, and a knowledge of these, together with the information on the numbers of electrons in completed groups which resulted from general atomic theory, showed that an unknown element of the fourth group must come before tantalum This element was shortly afterwards discovered in hafnium There was also, it was clear, an earlier unknown element in the rare earth group, which has been found in illinium. The group of rare earths was then known to be complete

The Periodic Law has thus assisted very materially in promoting discovery and has shown itself to be a truth of great extension and depth Mendeléeff himself said. "I have never once doubted the universality of this law, because it could not possibly be the result of chance" It is, in fact, the great guiding principle in the study of the structure of the atom

The Ether-Drift Experiment and the Determination of the Absolute Motion of the Earth*

By Prof Dayton C Miller, Case School of Applied Science, Cleveland, Ohio

THE ether-drift experiment first suggested by Maxwell in 1878 and made possible by Michelson's invention of the interferometer in 1881, though suitable for the detection of the general absolute motion of the earth, was actually applied for detecting only the known orbital component of the earth's motion For the first time, in 1925 and 1926, I made observations at Mount Wilson of such extent and completeness that they were sufficient for the determination of the absolute motion of the earth These observations involved the making of about 200,000 single readings of the position of the interference fringes

The ether-drift observable in the interferometer, as is well known, is a second order effect, and the observations correctly define the line in which the absolute motion takes place, but they do not determine whether the motion in this line is positive or negative in direction

At the Kansas City meeting of the American Association for the Advancement of Science, in December, 1925, before the completion of the Mount Wilson observations, a report was made showing that the experiment gives evidence of a cosmic motion of the solar system, directed towards a northern apex, but the effects of the orbital motion were not found, though it seemed that the observations should have been quite sufficient for this purpose[1]

The studies of the proper motions and of the motions in the line of sight of the stars in our galaxy have shown that the solar system is moving, *with respect to our own cluster*, in the general direction of a northern apex in the constellation Hercules This apex is near that indicated by the ether-drift observations as just reported, and seemed to be confirmatory evidence of its correctness Probably it was this that caused the continuation of the analysis of the problem, *on the supposition that the absolute motion was* to the northward in the indicated line All possible combinations and adjustments failed to reconcile the computed effects of combined orbital and cosmic motions with the observed facts

In the autumn of 1932, a re-analysis of the problem was made, based upon the alternative possibility that the motion of the solar system is in the cosmic line previously determined, but is in the opposite direction, being directed southward This gives wholly consistent results, leading for the first time to a definite quantitative determination of the absolute motion of the solar system, and also to a positive detection of the effect of the motion of the earth in its orbit

The absolute motion of the earth may be presumed *to be the resultant of two independent* component motions One of these is the orbital motion around the sun, which is known both as to magnitude and direction. For the purposes of this study, the velocity of the orbital motion is taken as 30 kilometres per second, and the direction changes continuously through the year, at all times being tangential to the orbit The second component is the cosmical motion of the sun and the solar system Presumably this is constant in both direction and magnitude, but neither the direction nor magnitude is known, the determination of these quantities is the particular object of this experiment The rotation of the earth on its axis produces a velocity of less than four tenths of a kilometre per second in the latitude of observation and is negligible so far as the velocity of absolute motion is concerned, but this rotation has an important effect upon the apparent direction of the motion and is an essential factor in the solution of the problem Since the orbital component is continually changing in direction, the general solution is difficult, but by observing the resultant motion when the earth is in different parts of its orbit, a solution by trial is practicable For this purpose it is necessary to determine the *variations* in the magnitude and in the direction of the ether-drift effect throughout a period of twenty-four hours and at three or more epochs of the year The observations made at Mount Wilson correspond to the epochs April 1, August 1 and September 15, 1925, and February 8, 1926

The point on the celestial sphere towards which the earth is moving because of its absolute motion is called the apex of its motion This point is defined by its right ascension and declination, as is a star, and the formulæ of practical astronomy are directly applicable to its determination from the interferometer observations The theoretical consideration of the determination of the apex of the motion of the earth has been given in a paper by Prof J J Nassau and Prof P M Morse[2]

Table 1 gives the right ascensions and declinations of the apexes of the earth's cosmical motion as obtained from the interferometer observations for the four epochs on the presumption of a southward motion, together with the right ascensions and declinations calculated upon the theory of an ether-drift

Table 1 Location of resultant apexes

Epoch	α (Obs)	α (Calc)	δ (Obs)	(Calc)
Feb 8	6^h 0^m	5^h 40^m	−77° 27′	−78° 25′
April 1	3 42	4 0	76 48	77 50
Aug 1	3 57	4 10	64 47	63 30
Sept 15	5 5	5 0	62 4	62 15

Apex of cosmic component $\alpha = 4^h\ 56^m$, $\delta = -70°\ 33'$

From these resultant apexes are determined four values for the apex of the cosmic component, which is the apex of the motion of the solar system as a whole. This apex has the right ascension $4^h 56^m$ and the declination 70° 33′ south

---

* Paper read before Section A (Mathematical and Physical Sciences) of the British Association meeting at Leicester on September 13, 1933

Continuing the astronomical description, having found the elements of the 'aberration orbit', these are used to compute the apparent places of the resultant apexes for the four epochs of observation. On the accompanying chart of the south circumpolar region of the celestial sphere (Fig 1), the large star indicates the apex of the cosmic motion, and the four circles show the locations of the calculated apexes These apexes necessarily lie on the closed curve representing the calculated aberration orbit, the centre of which is the apex of the cosmic component of the earth's motion Thus aberration orbit is the projection of the earth's orbit on the celestial sphere, which in this case is approximately a circle The observed apexes for the four epochs are represented by the small stars The locations of the pole of the ecliptic and of the star Canopus are also shown. The close agreement between the calculated and observed apparent apexes would seem to be conclusive evidence of the validity of the solution of the ether-drift observations for the absolute motion of the earth and also for the effect of the orbital motion of the earth, which hitherto has not been demonstrated

It may seem surprising that such close agreement between observed and calculated places can be obtained from observations of such minute effects, and effects which are reputed to be of such difficulty and uncertainty Perhaps an explanation is the fact that the star representing the final result for the February epoch is, in effect, the average of 8,080 single determinations of its location , the star for the August epoch represents 7,680 single determinations, that for September, 6,640, and that for April, 3,208 determinations

The location of the apex of the solar motion is in the southern constellation Dorado, the Sword-Fish, and is about 20° south of the star Canopus, the second brightest star in the heavens It is in the midst of the famous Great Magellanic Cloud of stars The apex is about 7° from the pole of the ecliptic and only 6° from the pole of the invariable plane of the solar system ; thus the indicated motion of the solar system is almost perpendicular to the invariable plane This suggests that the solar system might be thought of as a dynamic disc which is being pulled through a resisting medium and therefore sets itself perpendicular to the line of motion.

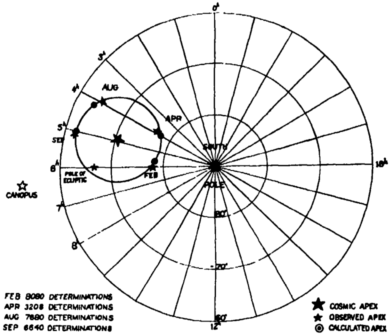

FIG 1 Observed and calculated apexes of the absolute motion of the solar system

It is presumed that the earth's motion in space is projected on to the plane of the interferometer, and the *direction* of this motion is determined by observing the variations produced in the projected component by the rotation of the earth on its axis and by the revolution around the sun Both the magnitude and the direction of the observed effect vary in the manner and in the proportion required by an ether-drift, on the assumption of a stagnant ether which is undisturbed by the motion of the earth through it But the observed *magnitude* of the effect has always been less than was to be expected, indicating a reduced velocity of relative motion, as though the ether through which the interferometer is being carried by the earth's motion were not absolutely at rest The orbital velocity of the earth being known, 30 kilometres per second, the cosmical velocity of the solar system, determined from the proportional variations in the observed effects, is found to be 208 kilometres per second

Table II gives the observed periodic displacement of the fringe system as the interferometer rotates on its axis, and the corresponding velocity of relative motion of the earth and ether

Table II Displacements and velocities

Epoch	Fringe Shift	Velocity (Obs)	Velocity (Calc.)
Feb 8	0 104 l	9 3 km /sec	195 2 km /sec
April 1	0 123	10 1	198 2
Aug 1	0 152	11 2	211 5
Sept 15	0 110	9 6	207 5

The last column gives the velocity to be expected in the stagnant ether theory on the presumption that the cosmic component and the orbital component are both reduced in the same proportion in the interferometer. The mean factor of reduction is $k=0\cdot0514$ The azimuth of the observed effect is subject to a diurnal variation, produced by the rotation of the earth on its axis The observed oscillations of the azimuth are in accordance with theory as to magnitude and time of occurrence, but for some unexplained reason, the axis of the oscillations is displaced from the meridian. In order to account for the results here presented, it seems necessary to accept the reality of a modified Lorentz-FitzGerald contraction, or to postulate a viscous or dragged ether as proposed by Stokes.

The results here reported are, notwithstanding a common belief to the contrary, fully in accordance with the original observations of Michelson and Morley of 1887, and with those of Morley and Miller of 1904–5 The history of the ether-drift experiment and a description of the method of using the interferometer, together with a full account of the observations and their reduction, has been published elsewhere[3].

Treasures of Carniola*

By CHRISTOPHER HAWKES, British Museum

THE work which has given this brief essay its inspiration and its title stands for three things of outstanding importance to all interested in the application of science to human history First, the unique value of the prehistoric treasures of Carniola and the surrounding provinces themselves, both in the narrower world of archæology and the broader one of man's history at large Second, the devotion by the late Duchess of Mecklenburg of her great resources to their methodical excavation from 1905 to 1914, after the district had for many decades been pillaged by indiscriminate fossickers, and so amassing a collection not only of enormous wealth, but also of unspotted scientific purity Third, the unparalleled feat of co-operation by which an American sale-room, acting for the late Duchess's daughter, has commissioned an international committee of prehistorians to work over the entire collection and perpetuate its authentic archæological groupings as lots in a free public sale in New York, at which it has been laid down that each lot is accompanied by its original inventory, excavation-records, plans, and other documents, the publication rights in each being reserved solely to its purchasers The volume now before us is the catalogue which embodies the archæological committee's work, and in enabling its publication the American Art Association Anderson Galleries have caused an outstanding contribution to be made to prehistoric science

The sale took place on January 26, and its results are still unknown to us It is evident that much of the collection will never re-cross the Atlantic, and it is known that of the European countries whose national museums may be enriched by shares, Great Britain has decided not to be one. But it is to be hoped that the purchasers, whatever their nationalities, will faithfully discharge their manifest obligation to publish their lots, with their documentation behind them, in detail and without delay The Mecklenburg sale may thus become an international precedent of the first importance in many scientific spheres.

The Duchess of Mecklenburg was born Princess of Windischgrätz, and came of a family long distinguished for services to archæology no less than to the Austro-Hungarian crown. By the greatest good fortune, their oldest estates in Carniola and Styria coincided with one of the richest and most important archæological centres in Europe She deserved well of her heritage. For it is safe to say that her excavations form one of the greatest single contributions ever made to the early history of man in this Continent How this is so is ably expounded in the long introduction to the catalogue by Dr. Adolf Mahr, who, it is needless to say, went to his present post in Dublin from Vienna.

The Early Bronze Age saw the birth of a round half-dozen of great cultural groupings in Europe, growing up in the earlier centuries of the second millennium B C Of these, Minoan civilisation dominated the Ægean from Crete Italy received a Bronze Age culture linked through the Alpine lakes with the barrow-builders of west-central Europe; and north and east of these three a civilisation of many provinces but a single broadly-conceived character stretched from the Balkan and Dinaric mountains to Saxony and Silesia. Equilibrium at last grew into tension, and rather before 1000 B C the tension snapped. The aspect of Europe was in a short time transformed The Minoan-Mycenæan civilisation crumbled to its downfall, accompanying upheaval in the Near East and all over south-eastern Europe The Etruscans thereafter left Asia Minor for Italy, to lay the foundations of its future, while from the great East European culture-area beyond the mountains migrating tribes had come pouring out, pressing into the Balkan highlands, and down to the Ægean, debouching on to the head of the Adriatic, penetrating the Swiss and south German plains and valleys, and absorbing their peoples in a varied but essential continuum reaching to

* Treasures of Carniola Prehistoric Grave Material from Carniola Excavated in 1905–14 by H H the late Duchess Paul Friedrich of Mecklenburg (*née* Princess Marie of Windischgrätz) Sold by Order of her Daughter, H H the Duchess Marie Antoinette of Mecklenburg Catalogue compiled under the direction of Dr Adolf Mahr (Dublin), assisted by Prof Raymond Lantier (St. Germain), Dr Gero von Merhart (Marburg a d L), Mr J M de Navarro (Cambridge), Prof Balduin Saria (Ljubljana), Prof Ferenc de Tompa (Budapest), Dr Emil Vogt (Zurich) and others Pp x+131+33 plates (New York American Art Association, 1934)

France and the British Isles. Meanwhile, from the south-east or east, there came into Europe the knowledge of iron.

The Early Iron Age that followed is the dawn of European history. The culture with which these great movements led it to open is round the Ægean called the Geometric, in Italy the Villanovan and Etruscan, and northwards of these the Hallstatt culture, from the great cemetery site in Upper Austria where it was first recognised, and where the Duchess of Mecklenburg in her turn came to excavate East of the central Alps, the peoples of the Hallstatt culture were predominantly Illyrians These Illyrians lay open to the east whence were coming the Scyths, they stretched down the Balkan Peninsula to the confines of Greece, they marched beyond the head of the Adriatic with Villanovan and Etruscan Italy, and to the north-west they mingled with the future Celts

Carniola, where the routes from Greece and Italy meet, with the ways east and north and west lying open behind, is the key to the whole great nexus Here, in cemetery after cemetery of surpassing richness, we can trace the development and appraise the character of the Hallstatt civilisation as never before, in the Duchess's great collection. It would be impossible to go into details here the total number of excavated graves is estimated at more than 1,300, and a reckoning of 20,000 individual objects may be short of the truth But if this mass of material, scientifically interpreted, helps us to understand the Hallstatt civilisation at its focal point, it opens our eyes to the unity of a great stretch of human history For, linked as it was to Etruscan Italy and Geometric Greece, with the shadow of the old Mycenæan Empire behind them, the Hallstatt civilisation was spread out over barbarian Europe, to give birth to that of the Celts whose conquests in east and west made way for the Roman Empire, and to last on meanwhile in Carniola, and more strongly still in the lands to south-eastward, until it passed under that Empire itself Standing here now, we can at once salute the spirit of Augustus and invoke the ghost of Agamemnon

Obituary

PROF J COSSAR EWART, F.R S

THE death of Prof James Cossar Ewart removes one who worked with distinction for more than half a century in the field of zoology and was a pioneer in the study of hybridisation and other problems of animal breeding

Prof Ewart was born at Penycuik, Midlothian, in 1851 and in 1871 entered the University of Edinburgh as a medical student After graduating in 1874 he acted for six months as demonstrator of anatomy under Turner and was then appointed curator of the Zoological Museum in University College, London. Besides adding numerous preparations both of vertebrates and invertebrates to the collection, he assisted Lankester, who had been appointed professor in University College in 1874, to organise the first course of practical zoology in the College, and in the absence of his chief in the summer of 1878 he was in charge of this class. During this period Ewart published papers on the structure of the lens and retina, on points in the anatomy of the lamprey and on the life-history of lower organisms, including *Bacillus anthracis*, and for this last work, presented as a thesis for the degree of M D (Edin), he was awarded a gold medal

At the end of the summer term of 1878 Ewart returned to Edinburgh and became a lecturer in anatomy in the extra-mural School of Medicine, but after about two months in this office he was appointed professor of natural history in the University of Aberdeen and began his work there in January 1879. In the same year he established a small marine zoological station near Aberdeen—the first marine laboratory in Britain—in which he and others conducted investigations during the next three years The most notable product of the station was the material for the Croonian lecture of 1881, by Ewart and Romanes, on the locomotor system of echinoderms

After three active years in Aberdeen, Ewart was appointed, in succession to Wyville Thomson, to the chair of natural history in Edinburgh, which he held for forty-five years—1882–1927 He reorganised the class of practical zoology, hitherto optional and attended by only a small proportion of the students, and established a more advanced practical course for students who were specially interested in zoology. He further developed the teaching and research in his Department by the institution of lectureships in embryology (in 1885, held first by George Brook and afterwards for twenty-six years by John Beard), in invertebrate zoology (1901) and in heredity and genetics (1910, to which Arthur Darbishire was appointed).

In 1882 Ewart became scientific member of the Fishery Board for Scotland, and during the next seven years was the author or joint author of about a dozen papers and reports on fisheries subjects including the natural history of the herring. Then followed the series of well-known papers, from 1888 until 1895, on the electric organ of the skate (*Raia*) and on the cranial nerves and lateral sense organs of this fish and *Læmargus*. He showed that the electric organ of the skate, discovered by Dr. James Stark of Edinburgh in 1844, was a developing and not a degenerating structure, and that in its most primitive condition, as seen in *Raia radiata*, the muscle fibres from which the electric elements are formed are less modified than in other species, and that in *Raia batis* the modification has proceeded so far that the adult electric organ presents little trace of its relation to muscular tissue

Ewart's investigations on the cranial nerves were undertaken at a time of considerable activity in neurological research and "trusting mainly to the old methods of the comparative anatomist" he gave an accurate account of the lateral sense organs and their nerve supply and of the macroscopic anatomy of the cranial nerves of *Læmargus* and, with J. C. Mitchell, of *Raia*. He had further preparations made for continuing his work on the cranial nerves, but was diverted by his interests in the development of the limbs of the horse. He showed in 1894 that in fœtal horses a digit composed of three phalanges was borne on the distal end of each of the splint bones which represent the metacarpals and metatarsals of the second and fourth digits, but that about the time of birth the phalangeal joints disappear, the phalanges become ossified and, early in the second year, fuse with their respective splints forming the "buttons". This was an important and interesting contribution in view of the reduction of these digits known to have occurred in the evolution of the limbs of the horse.

About 1895 Ewart began his work in animal breeding. It is to be remembered that Mendel's laws were not rediscovered until 1900, but Ewart devised careful experiments to throw light on some of the problems of cross breeding and inbreeding, on reversion and on telegony. The best known of these investigations were those in which mares of various breeds were crossed with a Burchell's zebra stallion. Ewart thoroughly studied the hybrids and presented the results, together with those of many other breeding experiments in a volume, "The Penycuik Experiments" (1899), which attracted much attention. The zebra hybrids formed an interesting exhibit at the Royal Agricultural Society's Show in York in 1900. His investigations to test the theory of telegony—that a sire may 'infect' the dam served by him and leave his mark on her subsequent offspring by other sires—led him to a negative result, and he showed that the appearances described could be explained as examples of reversion.

Several papers followed on different subspecies of horses, and on the origin and evolution of horses and ponies, and Ewart described (1906) the animal remains, more particularly of a considerable number of horses, found in the Roman fort at Newstead near Melrose. Papers on domestic sheep and their wild ancestors marked a further development of Ewart's work, and the renting from 1913 until 1921 by the University of Edinburgh of a farm at Fairslacks enabled him to conduct investigations for the improvement of the fleece of sheep, which brought him into contact with the woollen industry in Scotland; he also became an active member of the Council of the Wool Industries Research Association in Leeds. Ewart's expert knowledge was the chief factor which decided the Board of Agriculture for Scotland to constitute in Edinburgh in 1913 a committee on animal breeding. This committee was suspended during the War but was re-established in 1919 and in 1920 appointed Dr. (now Prof.) F. A. E. Crew as director of research, under whom the work in genetics and animal breeding has developed into a separate Department of the University.

The rearing of penguins in the Zoological Park in Edinburgh afforded Ewart the opportunity to study the sequence and the structure of the different types of feathers. In a paper in 1921 he discussed the origin and history of feathers, and he continued until about two years ago to devote attention to the relationship of feathers and scales.

Ewart had skilful hands and could make a good dissection and admirable drawings; early examples of his drawings are to be found in the plates of Turner's lectures on the placenta (1876). He was elected F.R.S. in 1893, was awarded the Neill Medal and Prize of the Royal Society of Edinburgh in 1898 in recognition of his investigations on telegony, and in 1928 received the honorary degree of LL.D. from his old University. He retired from his chair in 1927 and died in Penycuik on December 31, 1933. He is survived by his widow, a married daughter and a son, who is a surgeon in London. J. H. A.

DR. F. H. H. GUILLEMARD

FRANCIS HENRY HILL GUILLEMARD, whose death occurred on December 23, was born at Eltham in 1852. Travel and natural history made a strong appeal to him from boyhood onwards. At an early age he announced his intention of becoming a traveller and a doctor, and his first published work was an article on "Pigeons" in the *Boys' Weekly* in 1866. Destined for Rugby, he was kept at home between 1866 and 1868 owing to ill-health and afterwards went to a 'crammer' at Richmond. By this time he had become an habitué of Stevens' rooms in King Street, Covent Garden, never missing a natural history sale if he could help it and seeing there the great ornithologists of the day—Newton, Lilford, Howard Saunders and others. In 1870 he went up to Gonville and Caius College, Cambridge, where he read medicine under Humphry and Paget.

As an undergraduate, Guillemard made two journeys to the Orkneys, chiefly for bird study, which was one of the ruling passions of his life, and immediately after he had taken his degree he made a more ambitious trip to Lapland. At St. Bartholomew's Hospital he was clinical clerk to Patrick Black at the time when Robert Bridges was house physician.

Taking his M.B. degree in 1876, Guillemard entertained no thoughts of medical practice. Travel was his objective, and in 1877 he had the opportunity of exploring some little-known parts of Africa, trekking across the Transvaal and the Orange Free State in the old bullock-wagon manner and visiting the diamond fields in their early days. His articles on the ornithology of South Africa were published in the *Field* in 1880 and 1881, and the journey also provided the subject for his M.D. thesis, "On the Endemic

Hæmaturia of Hot Climates caused by the Presence of *Bilharzia Hæmatobia*", which was published in 1882. Guillemard's most famous journey was begun in 1881 when the *Marchesa* (schooner yacht of 420 tons, Mr C T. Kettlewell captain and owner) was commissioned The *Marchesa* reached Colombo in April 1882; from there she sailed to Singapore, Formosa, the Liu-kiu Islands, Japan, Kamschatka, the Sulu Archipelago, North Borneo and New Guinea. From the Malay and Papuan regions the *Marchesa* brought home a large collection of natural history objects, most of them obtained in the large islands of north-west New Guinea In particular, Guillemard was a passionate enthusiast for the birds of paradise, of which seventeen different species were found The whole collection of birds, numbering about 3,000 specimens, was described by Guillemard in the *Proceedings of the Zoological Society* of 1885, and on his return to England he settled in Cambridge with the view of writing a complete account of his journey "The Cruise of the *Marchesa*" was published in 1886 and was hailed as one of the best travel books in many years, such passages as that describing the first view of the Kamschatka group of volcanoes have made a permanent place for themselves in the literature of travel

Guillemard became a member of the British Ornithological Union in 1885 and, at the suggestion of Lord Lilford, went to Cyprus to make a study of the ornithology of the island Returning to Cambridge, he was the first holder of the lectureship in geography in the University, but owing to ill-health resigned the post almost immediately. A few years later, Guillemard settled at the Old Mill House at Trumpington, and there he lived until his death Though he held no official post in the University, he was one of its best known figures he was the general editor of the Cambridge Geographical Series and of the Cambridge County Geographies published by the University Press, he wrote the life of Magellan and the volume on Malaysia and the Pacific Archipelago in Stanford's "Compendium of Geography", he was active on the Botanic Garden and Fitzwilliam Museum Syndicates Above all, he had a wide circle of friends from whom he won affection as well as admiration With the passing of Henry Guillemard, Cambridge loses something that was exquisite and unique

WE regret to announce the following deaths

Dr D H Scott, F R S, honorary keeper of the Jodrell Laboratory at Kew in 1892–1906 and foreign secretary of the Royal Society in 1912–16, a leading authority on palæobotany, on January 29, aged seventy-nine years

Dr Henry S Washington, petrologist in the Carnegie Institution of Washington since 1912, an authority on the composition and classification of rocks, especially igneous rocks, on January 7, aged sixty-seven years.

Mr Edgar Worthington, formerly secretary of the Institution of Mechanical Engineers, on January 23, aged seventy-seven years

News and Views

Micro-ray Radio Link across the English Channel

ANOTHER milestone in the history of practical radio communication was reached on Friday, January 26, when Sir Philip Sassoon, Under-Secretary of State for Air, officially opened the world's first commercial 'micro-ray' radio service on a wavelength of 17 cm between the civil airports at Lympne, Kent, and St Inglevert, France. M. Delesalle, Under-Secretary of State for Air in France, was present at St Inglevert, and messages of greeting were exchanged, both by teleprinter and by telephone The inauguration of this service is the outcome of a demonstration given in March 1931 by Messrs. Standard Telephones and Cables, Ltd, who secured the contract for the Lympne installation from the Air Ministry The corresponding station in France was erected by the associated company—Le Matériel Télephonique, of Paris The actual wave-lengths employed in this radio link are 17 cm in one direction and 17 5 cm. in the opposite direction, and this separation enables duplex working to take place simultaneously by teleprinter and telephone. The teleprinter has been used on land-line commercial telegraph services for some years, and its application to radio communication on this occasion will enable messages to be sent and recorded at a speed of 60–70 words per minute

THE power generated at each transmitting station of new cross-Channel radio link is less than one watt, a special valve being employed to produce the requisite high-frequency oscillations, which are fed into an aerial about one inch long This aerial is situated at the focus of a small concave reflector which directs the waves on to a second reflector approximately 10 feet in diameter. The concentrated beam emanating from this arrangement is directed to the similar reflector system used for reception at the distant station. At the Lympne aerodrome, the aerial and reflectors are erected on the roof of a hangar, and are so placed as to command an optically clear path of the corresponding equipment installed on steel towers at St. Inglevert, 35 miles away. Duplicate aerial and reflector systems are employed for transmission and reception Special feeder lines are led down to the transmitting and receiving apparatus installed in the buildings below. This apparatus provides for the use of telegraphy and telephony in addition to the normal service to be carried on by means of Creed teleprinters. The object of this new radio service is to speed up the transmission of essential traffic messages, meteorological reports, and so on, involved in the operation of the cross-Channel air routes, and on account of its freedom from interference and its immunity from the effect of weather conditions, the service is likely to be highly successful and to add materially to the safety of air-travel between England and France

Gas Warfare and Civilian Populations

Dr. F. A. Freeth, of Imperial Chemical Industries, Ltd, addressing a meeting of the City of London Branch of the League of Nations Union on January 26, made some caustic comments on the subject of the position of the civilian population in chemical warfare The topic of chemical warfare has been so forced on the attention of the populace, he said, that the main danger in case of such an attack would be a psychological one Every chemical industry necessarily uses various kinds of poisonous materials, gaseous and otherwise, in its processes, but as a menace to the civilian population, they are not worth considering The really 'killing' gases are of low density and in consequence quickly disperse in the atmosphere As examples, Dr Freeth mentioned hydrocyanic acid and carbon monoxide, both of which are particularly subtle poisons Now the exhaust of an idling motor-bus contains about 6 per cent of carbon monoxide and, in consequence, the atmosphere of a narrow thoroughfare like Bond Street in London must, during a busy time, contain considerable quantities of the gas Yet owing to the ventilation provided by the air, it is not allowed to accumulate Of the heavier gases used in warfare, Dr Freeth mentioned chlorine, which requires for its use a quiet atmosphere and a gentle breeze in the desired direction, and mustard gas, which does not spread rapidly and on wet porous soils decomposes. The percentage of deaths to casualties from mustard gas during the War was less than four If during a gas raid, a man was able to keep his head sufficiently to shut all the windows of his house and put out the fires, he would be able to wait, in reasonable safety apart from a direct hit, until the authorities had dispersed the gas

Geography and World Citizenship

The Education Committee of the League of Nations Union has been meeting for some years and initiating and advising methods for making international questions and an international spirit a more integral part of ordinary school and college work It is largely through the activity of this committee that teachers as a profession stand so firmly by the League of Nations Meetings and conferences are arranged, lecturers sent out and publications of various kinds issued from time to time Of the latter, a brochure has just appeared (to be obtained from 15, Grosvenor Crescent, S W 1, price *4d.*) on "Geography Teaching in relation to World Citizenship". It is edited by Prof. J. F. Unstead with the help of a number of London teachers of geography and others, and will be approved by all engaged in similar work. The subject has always been regarded in schools as more obviously international than history, and for that reason much of what is said in the pamphlet will appear somewhat commonplace But there is no objection to enforcing emphatically some of the great commonplaces of human life and thought. It is useful to have set out clearly and in sufficient detail (as here) the main aspect of the inter-relationship of land and people and of the various peoples among themselves throughout the world.

The attitude of the various contributors to this pamphlet is sane and well-balanced, and they lay stress on those points in their theme which call for most emphasis at the present time Thus in relation to the mixture of races, it is pointed out that all over Europe—in Germany as well as elsewhere—there has been a blending of stocks, a 'give and take' in blood as well as in ideas But there is no attempt to pass over, or minimise, the reality or value of the contribution to the whole made by the various national units, based on a definite territorial region. The summary, for example, given of a supposed complete answer to the question, 'What should Italy imply to a well educated person ?', goes from an account of its physiography and natural products to its highest fruit in human genius—Dante, Leonardo, St Francis, Galileo and the rest The link is thus brought out between the teaching of geography and history, the more difficult subject It is understood that a further similar brochure will deal with history.

Lord Derby and the University of Liverpool

The completion by Lord Derby of twenty-five years as Chancellor of the University of Liverpool was celebrated on January 26 by a special congregation at which honorary degrees were conferred by the Chancellor upon Lady Derby, Lord Halifax (Chancellor of the University of Oxford) and Mr. Stanley Baldwin (Chancellor of the University of Cambridge) Lord Halifax was unable to attend. Following an address by the Vice-Chancellor (Dr. H J W Hetherington) on the growth of the University and the close associations, so long maintained, between Lord Derby, his immediate predecessors, and the University, the graduans were presented by the Public Orator (Prof Lyon Blease) for the degree of Doctor of Laws Following the graduation, Mr. Baldwin addressed the congregation and conveyed the congratulations of the University of Cambridge to the University of Liverpool upon the occasion. As the "newest of Chancellors", Lord Halifax conveyed congratulations in writing to both the University and the Chancellor upon the silver wedding of their partnership. In the evening Lord Derby, Lady Derby, The Earl of Crawford and Balcarres, members of the Derby family and the civic heads of the City of Liverpool and Merseyside were the guests at a dinner given by the University Association.

Indian Earthquake of January 15

The India Office has issued a general survey of the effects of the earthquake. The number of lives lost would appear to be in the neighbourhood of six thousand. The destruction of houses is greatest in the towns of North Bihar and Monghyr, especially Darbhanga, Muzaffarpur and Motihari Outside the towns, the principal effects are broken and obliterated roads, the collapse of bridges, floods and great fissures in the ground, from which mud, sand and water have issued, covering fields and crops with a devastating slimy deposit. The central area contains more than 300 square miles under sugar-cane. Though much of this has been saved, nearly all the sugar-mills have been destroyed. The chief difficulties at present are the supply of drinking water and the prevention of epidemics in towns and villages

Palestinian Remains at the British Museum

THE next special exhibition of prehistoric material at the British Museum will be opened on February 5 and will remain open for two or three months Two cases at the head of the main staircase, in the Department of British and Mediæval Antiquities, will be devoted to a display of a typical series from stratified caves near Mount Carmel, where excavations have been carried out by the British School of Archæology in Jerusalem and the American School of Prehistoric Research, with Miss D A E Garrod as field-director. Skeletal remains of palæolithic man will be shown (*Palæanthropus palestinensis*), and a sequence of implements from an early phase of the Palæolithic to Mesolithic, the latter being known as Natufian A special feature of the excavations is the blend of St Acheul and Le Moustier elements for a period , and a long succession of Aurignac types gives place to the post-palæolithic with a different and peculiar fauna. The abundant yield is incidentally useful for its similarities and contrasts to the better-known European industries, and special interest is attached to the beginnings of agriculture in Palestine

Velocity of Light

As was to be expected, the announcement which appeared in the press last summer (NATURE, 130, 25, July 2 , 277, Aug 20, 1932) to the effect that the latest experiments indicated a periodic variation in the velocity of light, has been construed in the sense that some seasonal instrumental error was at work. Science Service now issues an official confirmation of this view, given by the Mount Wilson authorities The report adds that the best value for the velocity of light is now 299,774 km /sec and that further analysis is only likely to change the last figure by one or two units The present investigation of the velocity of light is being carried out by Pease and Pearson, who are continuing Michelson's work and using the well-known rotating mirror method. It will be remembered that when Michelson used long base lines between mountain peaks, he found that irregularities in atmospheric refraction—the astronomer's "bad seeing"—interfered with the definition of the reflected image. The base is now *in vacuo*, in a pipe line a mile in length. To obtain more accurate results, it would be necessary to build a more stable pipe line, use quartz mirrors and employ elaborate timing devices.

Projected Electric Railways in Palestine

IN the *Electrician* of January 5 a description is given of a projected railway system for Palestine radiating from Jerusalem. Four new lines will radiate from a terminus at Jerusalem located outside the city on the northern side and east of the Damascus Gate Possibly recent economic developments in the country, the most important of which is the new harbour at Haifa on the Mediterranean, has tended to emphasise the isolated position of Jerusalem so far as railway facilities are concerned The northern line is to be 67 miles long, starting from the Jerusalem terminus, going through the Jordan valley, where the line descends to 500 feet below the Mediterranean level, finally getting to Tul Keram Junction on the main Haifa-Cairo line The eastern line (55 miles) would run from the terminus, crossing the River Jordan, passing through the Kalaat ez Zerka Station on the Hejaz railway to Ammam, the capital of Transjordan and the headquarters of the British Government's High Commissioner The southern railway (50 miles) would run through Hebron to Beersheba Finally, there would be a line (18 miles) from Wadi Fara on the northern line through Jericho to the potash works on the shore of the Dead Sea It is proposed to build a power station and a reservoir in Transjordan and another on the eastern shore of the Dead Sea to provide the electric current for operating the four railways The latter station would be necessary if an extension railway to the Red Sea should materialise Some years ago this project was discussed, the terminals of the line being Haifa and the ancient port of Akaba on the Red Sea. This would place Jerusalem on a direct sea-to-sea railway from the Mediterranean to the Red Sea. Possibly it might revive the ancient and prosperous traffic route from the Red Sea to the Levant of the times of Solomon and the Romans

Transmission of Power by High Tension Direct Current

AT the second World Power Conference held at Berlin in 1930, much consideration was given to international schemes for transmitting large amounts of power by high tension direct current The most ambitious of these schemes was to transmit one million kilowatts from the western fiords of Norway at a pressure of 500 kilovolts across Sweden and Denmark to the industrial regions in Westphalia, Germany. The great advantage of utilising power from the western fiords is that a uniform output of power all the year round could be obtained. It was proposed that the line should pass through Göteborg and Copenhagen to Hamburg, small amounts of power being tapped off at the two former cities, but the great bulk being delivered to Hamburg for distribution in the German networks. In a paper read to the Institution of Electrical Engineers on January 18, H. Rissik discussed the engineering aspects of the problem. He pointed out that with the same overhead lines, much larger currents can be used with direct than with alternating currents and the difficulties of working are much less with the former than with the latter. On the other hand, the methods of converting alternating current into high voltage direct current are still in the experimental stage, at least when dealing with power in bulk Lord Kelvin was a great advocate for the transmission of electric power by direct current, and although most of the difficulties in working with alternating current have been overcome since his time, it is interesting to notice that several engineers still think that direct current will be used for transmission in the future

Data of Social and Economic Problems

In a recent number of *Planning* (16 Queen Anne's Gate, London, S W.1) attention is directed to the lack of necessary data on many urgent social and economic problems. A civilisation has grown up under industrialism which calls for enormous resources of knowledge in order to operate it without constant and painful breakdowns Yet we neither possess the required knowledge nor are we making at present any adequate effort to get it, although its provision offers no insuperable difficulties Our whole attitude towards the question is still coloured by the prejudices and assumptions of a pre-scientific and pre technical age. It has yet to be recognised that the same technique which has produced electricity, wireless, fertilisers and new breeds of plants and animals can, if suitably adapted, produce those social, political and economic inventions which we so desperately need

While the industrial executive in Great Britain and elsewhere has come to recognise that provision must continually be made for new patterns and new techniques, there is no corresponding awareness or equipment for checking and improving the performance of, say, the machinery of government, the health services or the handling of traffic. Immense problems such as the modern scourge of noise, of smoke and chemical pollution in air and water, of street accidents, of crime, of destruction of amenities and many others are allowed to grow up unchecked and almost unobserved The problem is how to make effective the many demands for new knowledge which are at present frustrated because they do not promise profit to particular individuals or undertakings although they may involve great savings to the community Obviously one solution would be a great expansion of State-aided research, but much more thought and inquiry would be needed before concluding that this is the only, or the best, solution

A New Arctic Island

The discovery of a new island in the arctic is now a rare event, but in the *Geographical Review* of January, Mr V Stefansson describes what is probably such an occurrence. In September 1931 a party of Eskimo, searching for whales north of Alaska, came to an island on which they went ashore in a position of approximately lat 71° 20′ N, long 145° 30′ W This is about 85 miles north of Flaxman Island and due east of Point Barrow. The island was reported to be about half a mile long and of the same width and to rise to an altitude of about fifty feet. There was some vegetation but no driftwood Mr Stefansson vouches for the reliability of the Eskimo Takpuk who led the party and whose name has been given to the island Further, he discounts the suggestion that the island was merely earth on floating ice That part of the Beaufort Sea has been little explored though the nearest soundings, some twenty-five miles to the west, show deep water The question arises as to the possibility of Takpuk Island being Keenan Land, reported in the 'seventies of last century and placed in various longitudes in about lat 73° N, but this seems more than doubtful Photographs of Takpuk Island are reproduced with the article

The *Australian Geographer*

The format has been remodelled and the scope changed of the *Australian Geographer*, the periodical published by the Geographical Society of New South Wales It is hoped now to publish it more often than once a year and to give special consideration to the work of Australian writers on the geography of the continent A special feature will be the continuance in every issue of a bibliography of Australian geographical literature. This feature, which begins with the year 1926 in the current issue (No 1, vol 2), should prove of considerable value Another valuable article is that by Dr. M Holmes in the Australian geographical environment, which treats the subject in much detail

Philosophy and Everyday Life

The organ of the Philosophical Society of England, the *Philosopher*, enters on its twelfth year of publication under new editorship and in a new and attractive format As is pointed out in the opening article, the special branches of science have found exponents capable of interpreting their many recent advances to the general reader, and it is the purpose of the *Philosopher* in a similar way to interpret current thought in philosophy and to indicate its contacts with the world of to-day Thus in the issue before us there is an article on "Reason in Action" by Prof John Macmurray, another on "Reflection and Common Sense" by Prof A E Heath and another by Paul Painlevé, the distinguished French mathematician, philosopher and statesman who died towards the end of last year, on "Civilisation and Modern Science" Students of philosophy will perhaps turn more readily to the "Courses of Study", where notes are given on various aspects of the subject, with suggestions for further reading There are also reviews and notices of recent books, a section on educational intelligence, a record of meetings of the Philosophical Society and so on. The journal has thus a double appeal, to the layman and to the student, and at the modest price of 6*d*. should have a wide circle of readers. Copies of the *Philosopher* can be obtained from the Honorary Secretary of the Philosophical Society, 13 Woodlands Road, London, S.W 13

Physica

The first number of the new Dutch periodical *Physica* (December 1933, pp. 96, published by Martinus Nijhoff, The Hague, 25 guilders yearly) contains a number of interesting papers. The paper by de Haas and his co-workers on the attainment of very low temperatures by adiabatic magnetic changes is referred to in our Research Items (p 181) Druyvesteyn describes experiments on the low-voltage arc in sodium vapour. The absorption of the *D* lines was measured in the arc and the reversal of the *D* lines against a continuous source at variable temperature was observed. The results show that the number of excited sodium atoms is about 12 per cent of the number of the normal atoms, and that the number of Na$^+$ ions is several times the [illegible]or of normal atoms The theory of light emission na[illegible]seous discharges is discussed by W De Groot [illegible] Hoel describes a quartz-fluorite combination lens [illegible]uch is achromatic and spherically connected. It intended for focusing light on a thermocouple with unit magnification P Cohen Henriquez describes a micro apparatus for determining the dipole moment of organic solutes The apparatus may be used with a few milligrams of material. The ratio of the lithium isotopes has been determined by intensity measurements of the fine structure of the Li resonance line by Ornstein, Vreeswijk and Wolfsohn. Van Kreveld describes an empirical summation law for a photographic plate exposed to light of two or more colours, and Van der Pol and Weyers describe the approximations known as Tchebycheff polynomials. The papers are in English or German, and in some cases German papers are provided with an abstract in English.

Recent Acquisitions at the British Museum (Natural History)

AMONG the recent acquisitions at the Natural History Museum the Department of Zoology has received as a donation from Mrs. Charles Buckley and Mr. Godfrey R Buckley the mounted head of a cow of the Chartley breed of cattle. Chartley Park was formed by enclosing about 1,000 acres of the forest of Needwood in the reign of Henry III, when a number of half-wild cattle, which then roamed throughout the district, were driven in and enclosed in the Park. Two important additions have recently been made to the beetle collections in the Department of Entomology, namely the Donisthorpe collection of British Coleoptera and an Australian collection purchased from Mr W du Boulay. The former contains upwards of 22,000 specimens, and is of especial interest in that it is accompanied by the most complete set in existence of the numerous British insects (mainly beetles) and other arthropods that live in association with ants and are known as myrmecophiles The du Boulay collection, which numbers only 352 specimens, consists, however, entirely of beetles actually found inhabiting ants' nests in various parts of Australia by Mr. du Boulay over a period of sixteen years Mr R E Turner, working in South Africa, has collected and presented to the Museum some 8,000 insects of various kinds, principally small bees and wasps ; and from the mountains of New Guinea Miss L. E. Cheesman has collected for the Museum upwards of 18,000 specimens. Miss M Graves, M P , has presented to the Geological Department some portions of the egg-shell of a small horned dinosaur, *Protoceratops andrewsi*. The South Australian School of Mines and Industries has presented an end-slice of a large mass (2,520 lb) of meteoric iron found in 1909 at Murnpeowie, South Australia, previously represented in the collection only by a cast of the whole mass

Sunday Lectures at the British Museum (Natural History)

FOR the benefit of visitors to the Natural History Museum on Sunday afternoons who may wish for fuller information about the various branches of natural history than may be obtained by casual wandering through the galleries, the Trustees of the British Museum have arranged for two lectures each afternoon at 3 and 4 30, to be given usually by a member of the scientific staff Lectures illustrated by lantern slides will be given in the Board Room, and the remainder in one of the galleries The opening lecture will be on Sunday, February 4, the lecturer being Capt Guy Dollman, who will speak on the great game animals of Africa and will show a number of lantern slides On succeeding Sundays lectures will be given by Dr W E Swinton on earthquakes, Mr Maurice Burton on seashore animals (both in the Board Room), and Mr J R Norman on the Fish Gallery Admission to the lectures is free

THE Department of Botany of the Natural History Museum has received a bequest of the herbarium of the late Ashley H Maude. The specimens are well mounted on about 5,000 sheets and are in good condition, contained in four cabinets They are chiefly European but there are also collections from Algeria, Cape Colony and the Canary Islands The Godman Trustees have presented 534 specimens of flowering plants collected by Mr F. Ludlow and Capt G Sherriff in Bhutan The area traversed is one which is not very well known botanically and as each 'number' comprises a good series of well-dried plants the collection is of great value A number of seeds were also collected, and these have been distributed This year's collecting season in Nepal was ruined by the monsoon and consequently only fourteen specimens were collected by Prof K. Sharma Those were presented to His Majesty the King and placed by him on loan in the Department of Botany Although the number is small it includes several very important horticultural plants

Empire Museums and the Carnegie Corporation

IT is gratifying to learn (from the December number of the *Museums Journal*) that the Carnegie Corporation has decided to grant substantial sums for the development of the museums of the Empire, following upon the Empire Survey of Museums, to which reference has been made in these notes. Already grants totalling 50,000 dollars have been made in Canada, and it has just been made known that similar sums have been set aside for South Africa, Australia and New Zealand These will be administered by local committees. In addition to the 200,000 dollars thus earmarked, the Carnegie Corporation has also decided to appropriate 63,000 dollars to the Museums Association for a programme of museum development in Newfoundland, Southern Rhodesia and the Colonies.

A Direct Reading Universal Drawing Compass

MR. THOROLD, 20, Rathbone Place, W 1, sends us particulars of a new instrument which is a combination of scale and compass The compass points travel on a beam carrying interchangeable scales. The two points terminate in movable heads on the beam which are adjustable, one possessing a micrometer The instrument is also supplied with calliper points for external and internal measurements The maker claims that great accuracy is obtainable, and for fine drawing in the field of physical science and engineering the invention seems likely to be valuable The cost of the instrument is £7 7*s*

Austrian Ethnographical Expedition to West Africa

AN expedition, of which Dr Ralph Elber, of the Institute of Egyptology and African Studies, is the leader, left Vienna, according to a communication issued by the Reichszentrale fur Wissenschaftliche Berichterstattung, Berlin, early in January for Sierra Leone, whence it will proceed to Liberia for the purpose of exploring the interior of the country and observing the little-known tribes of that region Special attention will be given to the study of the religious and magical beliefs of the tribes and their languages, which are virtually unknown The results of this expedition should be of special interest in view of present lack of knowledge of the area, its inhabitants and natural history It is also hoped to add to the map particulars of one of the last uncharted areas of Africa

Pittsburgh Award of the American Chemical Society

THE Pittsburgh Section of the American Chemical Society has selected Dr Ralph E. Hall, director of the Hall Laboratories, Inc , Pittsburgh, Pa , as the recipient of the 1933 (the first) Pittsburgh Award This honour, which will be conferred on Dr. Hall at the sectional meeting on February 15, is in recognition of his distinguished service to chemistry and humanity, particularly his contributions to the fundamental knowledge of boiler-water reactions and their applications to the practical solution of boiler-water problems, his discoveries and technical accomplishments in the beneficiation and conditioning of water for industrial and domestic use, and his developments in the production of chemicals for these purposes The Pittsburgh Award is represented by a plaque of gold, on which the relation of chemistry to industry is symbolised

Announcements

SIR WILLIAM LARKE, K.B E , Director of the National Federation of Iron and Steel Manufacturers ; Prof. Edward Mellanby, F.R S , Secretary of the Medical Research Council ; and Mr Leonard Woolley, Director of the Joint Expedition of the British Museum and of the Museum of the University of Pennsylvania to Mesopotamia, have been elected members of the Athenæum under the provisions of Rule II of the club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, the arts or for public service.

SIR ARTHUR EDDINGTON will deliver the Rickman Godlee lecture at University College, Gower Street, London, W C 1, on Friday, February 16, at 5 30 p.m. The subject of Sir Arthur's lecture will be "The Constitution of the Stars". The lecture will be open to the public.

PROF A ZIMMERN, Montague Burton Professor of International Relations in the University of Oxford, is giving a course of six lectures (Muirhead Lect· in Social Philosophy) at the University of Birm ham on Thursdays, beginning on February 1, "Britain and the World Crisis".

MISS NINA SYMINGTON, daughter of the late Pr . Symington of Belfast, has bequeathed the residue of her estate, amounting to some £9,000, to be known as the Johnson Symington Memorial bequest, to the Anatomical Society of Great Britain and Ireland for anatomical research

THE Council of the Institution of Naval Architects has awarded the Gold Medal for the year 1933 to Eng.-Capt. S. R Dight, for his paper on "Naval Water-Tube Boilers Experiments and Shop Trials" ; and the premium to Dr. George Hughes, of the William Froude Laboratory, for his paper on "The Effect of Wind on Ship Performance".

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A chemical assistant to the advisory chemist in the Department of Agriculture, University of Cambridge —The Secretary, School of Agriculture, Cambridge (Feb 10). A junior assistant (chemist) in the Royal Gunpowder Factory, Waltham Abbey—The Principal Clerk, Central Office, Royal Gunpowder and Small Arms Factories, Enfield Lock, Middlesex (Feb 10). A head of the Department of Civil Engineering and Building, and a head of the Science Department in the Lester School and Institute, Shanghai—Messrs. Viney, Price and Goodyear, Empire House, St. Martin's-le-Grand, London, E C.1 (Feb. 20). A director of the University School of Librarianship at University College, London—The Academic Registrar, University of London, S.W.7 (March 1). A University lecturer in moral science in the University of Cambridge—The Secretary of the Faculty Board of Moral Science, King's College, Cambridge (March 1). A University lecturer in forestry in the Department of Agriculture of the University of Cambridge—The Secretary, School of Agriculture, Cambridge (April 14). A keeper of the Museum at the Victoria University of Manchester—The Registrar (April 30). A research assistant (male) in the Cancer Research Department of the Westminster Hospital, Broad Sanctuary, London, S.W.1—The Secretary. A registration officer and statistician, and a finance officer and accountant for the Potato Marketing Board—The Secretary, Potato Marketing Board, 45 Bedford Square, London, W.C.1.

Designation of Heavy Hydrogen

IN a recent issue of NATURE (132, 955; 1933) Lord Rutherford has suggested that the heavy ‘ope of hydrogen be named diplogen, instead of name deuterium proposed by us This was one me considered by us before we published our uggestion of the names protium and deuterium for the two isotopes of hydrogen.

Our objection to this name arises from the difficulty of naming compounds which contain two of the heavy hydrogen atoms. Thus the compound $NH^1H^2_2$ would be called di-diplogen mono-hydrogen nitride The part of this name which we think is unfortunate is the repetition of the syllable ‘di’ in the name, and it was for this reason that we discarded this name for the heavy isotope Also, we believe that the two isotopes of hydrogen should be treated symmetrically, and the corresponding name, haplogen, for the hydrogen of mass 1, did not appeal to us. Moreover, both names have a rather forced meaning ‘To generate double’ and ‘to generate single’ seem to have no evident applicability to the hydrogen isotopes such as the corresponding meaning of the word hydrogen has

The objection to the name deuterium for the substance H^2 and the name deuton for its nucleus, seems to be founded upon the possibility of confusing the word neutron and the name deuton Perhaps the use of the name deuteron would eliminate this difficulty. It is interesting indeed that American scientific workers do not have any such difficulty so far as we are aware.

It may be of interest to readers of NATURE in connexion with the discussion of names for this substance if we list some of the names considered by us before we proposed these names These include :

Haplogen for H^1 and diplogen for H^2. These names were discarded for the reasons given above

Hydrogen for H^1 and bar-hydrogen for H^2, with the symbol $\bar{H}$ for the latter This we discarded because it is a four-syllable word and because people generally seemed to dislike the sound of it Thus di-bar-hydrogen would occur in some chemical compounds and the two prefixes seem very awkward.

Barogen for H^2 and pycnogen for H^2. Both these names were eliminated because they did not sound euphonious and also because we feared that it was emphasising the increased density of the compounds too much.

Iso-hydrogen for H^2. This was eliminated because the term iso is a common term for naming organic compounds.

Dygen for H^2. We eliminated this name because of the impossibility of making any of the usual chemical combining terms.

We finally agreed upon the names protium and deuterium because they place the two isotopes of hydrogen as equal, both being hydrogen, and because of their meaning as first and second, and because we felt they were the most descriptive of these names. We were influenced in the selection of deuterium by the preference of others for the name deuton, though we preferred to use the entire Greek stem rather than to abbreviate it

As Lord Rutherford states, the question of naming this isotope is so important that a general discussion of the name is very desirable at this time. We are not only giving a name to a single isotope, but we are perhaps also introducing a system for naming other isotopes in the future Whatever names are finally selected, we do believe that both isotopes of hydrogen should be named and the name hydrogen be used to apply to both of them, and that this principle be adhered to in the future in naming any other isotopes This question of course is not important at the present time, but we think that it would be too pessimistic to believe that other isotopes will not be separated in quantity in the future

CHEMISTS cannot admit such fearsome wild fowl as *Diplogen* to their sanctuary of elements -elements no longer, subject as they are to protono-decapitation and reheading to satisfy simple sums Diplogen is an offence against the usages of the house chemical, philologically unsound and bereft of reason The *gens* are all gentles with specific functions . hydrogen the *gen* of water ; oxygen the *gen* of acid , nitrogen the *gen* of nitre Diplogen, the gen of twins, can have no place in such company Diplog*en*, if you will, as it has so gone to the heads of physicists—but Diplog*en*, never ! It's a twin not a twinner Fish will leave the waters, if they learn that such a monster is around

Why not simply *Deuthydrogen*, as it is the second term in the hydrogen series ? Should a Triton appear among these minnows, it will be Trithydrogen We shall then be naming it in accordance with the principle adopted in homologous hydrocarbon series. After all, the American parents alone have the right to decide what the child's name shall be—whatever Dr Aston may assert Still, he is scarcely to be ranked as an authority—as he will not recognise distinction between ‘composition’ and ‘constitution’. Much measuring has made him oblivious of meanings

We notice elsewhere a suggestion of the name *Woollywestium*, Ww. Such a name would invite its wearing next the skin, whilst taking cognisance of a Californian birthplace.

We cannot allow physicists to muddle our language : as they have done in their varied misuse of Faraday's incomparable term ion , in their continued failure to distinguish between atom and molecule—to give only two examples Their run of the significance of ion is a disaster, an insult to Faraday's memory , our literature is thrown into entire confusion thereby.

Activities of Life and the Second Law of Thermodynamics

I AM very glad to have elicited Prof. F. G Donnan's critical views (NATURE, Jan 20, 99) on my suggestion as to life and thermodynamics, but confess I remain unconvinced by his arguments

Prof Donnan challenges my neglect of the body metabolism or fuel oxidation which, as he says, necessarily accompanies the arrangement or disarrangement of material objects by human activities, considering that such chemical changes may produce an increase of entropy sufficient to offset any decrease produced by human intelligence No doubt it may, but I cannot see that these two effects are "functionally inter related" or in any way suitable subjects for comparison Given perfectly level and frictionless railways, a man may move millions of tons of matter, and thereby decrease the entropy of the world enormously, without incurring any corresponding increase of entropy through the combustion of food or fuel Any increase of entropy which occurs in practice is a mere side-issue, an accident resulting from the impossibility of realising ideal conditions, and so should not enter into the theoretical discussion at all

A further increase of entropy might of course occur if the mental effort of arranging objects caused an increase in bodily metabolism I believe orthodox physiology teaches that any such effect is inappreciable, but it is in any case obvious that it cannot be relied on to offset the decrease of entropy resulting from intelligent arrangement We cannot, for example, suppose that the man who steers the *Mauretania* consumes food-energy at a rate comparable with 100,000 h p more than normal, merely because he is guiding a ship of that horsepower

Prof Donnan's parallel from crystal growth seems to me to fail through identifying "increase of organisation" with "decrease of entropy". The two are equivalent so long as potential energy is unimportant, but when this becomes preponderating, as in a crystal, maximum entropy may well demand regular packing, and so *maximum*, not minimum, organisation.

J. H JEANS

Crystal Structure of Lanthanum, Cerium and Praseodymium Hydrides

THE original metals were La α (hexagonal close packed arrangement, $a_0 = 3\ 75_7$ A, $c/a = 1\ 61$), Ce β (face centred cubic, $a_0 = 5\ 14_6$ A, Pr α (hexagonal close packed, $a_0 = 3\ 65_2$, $c/a = 1\ 61$)

Lanthanum annealed in vacuum at 350° C, for several days, furnished powder photographs similar to those described very accurately by Zintl and Neumayr[1] for the β phase (face centred cubic) of this element I have noticed that by removing a very thin outer layer from the annealed specimens, the latter gave again the characteristic photographs of the α modification, that is, it was merely a surface phenomenon

Praseodymium subjected to the same thermal treatment did not modify its structure The specimens annealed in vacuum at 750° C for 48 hours furnish photographs of a somewhat different aspect, but yet not corresponding to a possible allotropical β form

The difficulty of hydrogen absorption increased in the order cerium, lanthanum, praseodymium In any event, the thermal treatment which was necessary to start the hydrogen absorption, repeated in vacuum on some specimens of the last two elements (α modification), did not change their crystal structure

The hydrides of the above mentioned metals all showed face-centred cubic lattices, with sizes larger than those pertaining to the real or possible β phases of the original pure elements

Lanthanum hydride furnished in one case photographs revealing the simultaneous presence of two face-centred cubic phases, having for side $a'_0 = 5\ 62$ A., $a''_0 = 5\ 70$ A. (hydrogen absorbed, about 140 c mm per gm) Generally, however, only one face-centred cubic phase appeared, having a of $a_0 = 5\ 62\ 5\ 63$ A (hydrogen absorbed, ab 200 c mm per gm) If the hydrogen was remov by heating and a vacuum pump (at 1 mm pressure) the size of the lattice seemed to increase a little (at 530° $a_0 = 5\ 65$ A, at 700° slightly greater values)

Cerium hydride showed a lattice with side $a_0 = 5\ 61_3$ A which by removal of the hydrogen in vacuum at 530° split up into two similar phases of slightly smaller dimensions

The lattice of praseodymium hydride (absorbed hydrogen, about 165 c mm) was only slightly larger (some hundredths of an angström) than that of metallic cerium, that is, than that which a hypothetical β phase of praseodymium would give, according to the small existing difference between the atomic diameters of praseodymium and cerium in the α phase

Magnetic Anisotropy of Graphite

GRAPHITE is known from the investigations of Owen, Honda and others to exhibit an exceptionally large magnetic anisotropy. The susceptibilities of the natural crystal along its hexagonal axis and along perpendicular directions are, according to Honda[1]·

$$\chi_1 = -14\ 2 \times 10^{-6}\ ;\quad \chi_2 = -2{\cdot}2 \times 10^{-6}$$

respectively, per gm., χ_1 being thus more than six times χ_2 Recently Goetz and his collaborators have found a much higher value for the ratio χ_1/χ_2 Chemically treated pure graphite powder is dispersed by them in a solution of gum Dammar in benzene, the solution is placed in a strong magnetic field and the benzene is allowed to evaporate. All the graphite particles in the solidified medium will then naturally be oriented in the same manner, namely, with their hexagonal axes normal to the direction of the imposed field From susceptibility measurements on this medium they found[2] for χ_1/χ_2 a value of 13 2 Later[3], using graphite particles dispersed in this manner in a solidified solution of agar, they obtained a still higher value, namely, 18 Their more recent estimate[4], obtained from a similar suspension of graphite particles in gelatine, is so high as 28. It would thus seem desirable to determine the anisotropy of graphite by an independent method.

The following measurements made with some good specimens of Ceylon graphite, by Messrs B. C. Guha and B. P Roy in this laboratory, may therefore be of interest The method adopted in these measurements was the same as was described in previous papers[5]. By suspending the crystal, with its hexagonal axis horizontal, at the end of a calibrated quartz fibre, in a uniform magnetic field, and measuring the couple due to the magnetic anisotropy of the crystal, the *difference* between the two principal susceptibilities, namely, $\chi_1 - \chi_2$, was determined. With the same suspension, the absolute value of χ_2 was measured by magnetically balancing the crystal in a field of large non-homogeneity, against an aqueous solution of potassium iodide, the susceptibility of which could be adjusted by suitable dilution.

Altogether ten different crystals were measured for $\chi_1 - \chi_2$, and the values obtained ranged from $-21 8 \times 10^{-6}$ to $-23 0 \times 10^{-6}$ per gm. The values for χ_2 varied about a mean value of $-0 4 \times 10^{-6}$ Hence the principal susceptibilities of these crystals per gm are:

$$\chi_2 = -22 8 \times 10^{-6}, \chi_1 = -0 4 \times 10^{-6}$$

Rate of Ionisation of the Atmosphere

THE rate of atmospheric ionisation (q), as calculated from observations of small ions and nuclei, has been found to attain a maximum at approximately 18 hours G M T in such widely separated localities as Glencree[1], Washington[2] and Canberra[3]

Recently a series of direct observations of q has been completed at the Commonwealth Solar Observatory A large 'unshielded' ionisation vessel was refilled with the outer air at hourly intervals and the saturation currents measured The hourly means of observations extending over forty complete days were

G M T	q	G M T	q	G M T	q	G M T	q
0	25 6	6	21 5	12	29 0	18	37 8
1	23 6	7	23 8	13	32 0	19	35 4
2	21 3	8	24 1	14	32 0	20	35 1
3	21 5	9	26 0	15	33 4	21	31 9
4	21 4	10	27 6	16	35 9	22	32 0
5	21 4	11	28 4	17	38 0	23	29 2

The columns headed G M T show the hour at which the filling of the vessel was completed; those headed q give the rate of ionisation of the air in the vessel in ion pairs per cubic centimetre per second

A ten-day series of observations, made upon a sample of air which had been confined in the vessel for four weeks, showed the background ionisation to be 15 6 ion pairs per c c per second, and to be constant to within ± 1 per cent throughout the day

Although the above figures may be subject to certain small corrections, they show that the rate of ionisation of the lower atmosphere undergoes considerable diurnal variation

Whether the approximate agreement of the maximum at Glencree, Washington and Canberra is more than a chance coincidence can be determined only by observations in other localities.

Ionospheric Measurements in the Polar Regions

THIS note is a brief account of the results of wireless observations made in connexion with the International Polar Year 1932–33 at Murmansk (lat 68° 56′ N, long 33° 05′ E) in the U S S R during June, July and August 1933 This work was organised by the Leningrad Section of the Institute for Scientific Research of the People's Commissariat for Communication in association with the Central Geophysical Observatory and was carried out under my direction

A special system with two 150-watt tubes was designed in order to send out short pulses of 20 kw energy This was accomplished by using a condenser charged to high tension by a rectifier. By means of a rotary spark gap, this condenser was discharged fifty times per second through the plate circuit of the tube oscillator, in which short oscillations of great power were thus produced The rest of the time the condenser was not connected to the oscillator and the charge was gradually stored up. Thanks to this method, it has been possible to carry out experiments under the conditions of an expedition, using but a small power

The observations were made with a cathode ray tube, the circular motion of the spot was caused by the current of a small alternator, driven on the same shaft as the transmitter discharger The transmitter and the receiver were separated by a distance of three kilometres and connected by wire

Several unusual phenomena were found which must have been due to specific conditions of the ionosphere in polar regions Shortly, the results obtained may be summarised as follows

In the polar regions during the summer solstice and for some time after, both the main reflecting layers *E* and *F* of the ionosphere are found to exist. The *E* layer is in general less active than in temperate latitudes and therefore but seldom capable of screening the *F* layer It is mostly in evidence for waves of 75 m and 110 m around midnight and occasionally by day

The daily variations of ionisation are in some cases similar to those in temperate latitudes, whereas sometimes they were of an opposite character. Pictures for noon and midnight were nearly always alike, but differed from those for intermediate hours.

Very complex reflections from the upper region are due to the stratified or undulatory structure of the ionosphere Rapid motion is found to exist in this layer

No increase of the shielding effect of the *E* layer and no changes in absorption have been observed at times when this layer dropped to a height of 65 km This seems to indicate that in this case such a low level of the *E* layer is due to changes in the distribution of gas pressure at great heights and corresponds to a deep barometric minimum of the upper atmosphere.

Periods of complete cessation of echoes have been observed, which lasted sometimes for several hours; sometimes, however, the echoes were absent only for one minute or even less The picture of reflections before and after such a short absence of echoes was found to be the same

Such observations suggest that this disappearance of echoes is due to some factor, having the character of a screen, placed between the observer and reflecting layer at an intermediate height, or, it may be said, that a separate 'absorbing layer' is produced at times below the *E* layer, at a height probably less than 65 km.

The character of these phenomena offers some basis for explanation of the structure of this layer: it may be composed of separate moving masses, shielding the Kennelly Heaviside layer (as does a cloud, when it covers the sun) or produced by some variable agent, and is able to appear and disappear very rapidly Further light might be thrown on this question by comparing moments of echo cessations at two points not very far apart

No correlation was found between the changes taking place in the *E* and *F* layers and the presence or absence of the absorbing layer Therefore the absorbing layer must be considered as an independent formation quite apart from the *E* layer and due to other agencies than the *E* and *F* layers

There is undoubtedly direct correlation between the phenomenon of echo cessation and magnetic activity.

The difficulty caused by magnetic storms of maintaining continuous wireless communication over high latitudes may be attributed to the existence of the absorbing layer

These results agree in general with those obtained by Prof E V Appleton during his observations at Tromsø (NATURE, Sept 2, p 340)

Basking Shark in the Bab el Mandeb

WHEN passing through the Strait of Bab el Mandeb in November 1933 on board the Dutch mail steamer *Johan van Oldebarnevelt*, my attention was directed to the fact that a big fish was fastened on the bow of the vessel So long as the latter continued running at full speed, the shape of the fish could not well be determined. It was evident only that the enormous tail was turned to the right side and could be seen moving now and then as if the fish were still alive, the tip reaching the surface of the water occasionally

After the vessel had diminished its speed and finally stopped, what I had suggested was confirmed, namely, that we were dealing with the big 'whale shark' or 'basking shark' (*Rhineodon typus*) The shape and the very conspicuous colour-pattern (white lines, intersecting each other at right angles, and white blotches on a black ground) could be very clearly distinguished The animal had been 'rammed' by our vessel in a similar way to that already recorded by E W Gudger for the same species in a few cases, just behind the left pectoral fin, so that it could not free itself and remained fastened with the left side of the back to the sharp bow of the ship After the ship had stopped the fish got free, showing a big wound on the left side and sinking down slowly into the depth I could not state with certainty whether it was still alive. I estimate its length at 6–8 metres.

As stated above, similar cases of this kind have been recorded by Gudger, namely, one that happened near Abrolhois Light off the coast of Brazil, and another near the mouth of the Sassandra River in the northern part of the Gulf of Guinea

New Methods for Direct Visualisation of Ultra-sonic Waves and for the Measurement of Ultra-sonic Velocity

MEASUREMENTS of ultra-sonic velocities in liquids can be easily made by the method of Debye and Sears or Lucas and Biquard[1], who used the periodically alternating densities produced in a liquid by ultra-sonic waves as an optical grating. Such measurements have been made in this department at the suggestion of Prof H. Falkenhagen, who wanted more precise data on the compressibilities of electrolytic solutions. In the pursuit of these researches we have found it preferable to visualise this 'optical grating' directly instead of using it for the diffraction of light. Details of the new method will be given in a forthcoming publication in the *Zeitschrift für Physik*. The picture reproduced as Fig 1 is a photomicrogram of a stationary ultra-sonic wave formed at a convex mirror in xylol, frequency about 4500 kHz It is possible to measure the distance of the nodal lines very precisely. By measuring a great number of nodal lines, we are able to make measurements of ultra-sonic velocities in liquids with the highest precision

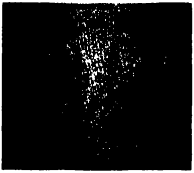

FIG 1 Stationary ultra-sonic wave formed at a convex mirror

In order to clear up some theoretical problems on which such successful pioneer work was done by R. W Boyle[2], it is necessary to use progressive waves instead of stationary ones We succeeded also in the direct visualisation of ultra-sonic progressive waves by using a high-frequency stroboscope based on the principle of the Kerr cell. This enables us to study a sound field without disturbing the field itself We can also measure directly with a microscope or a comparator the distance of subsequent wavefronts of progressive ultra-sonic waves This is another new method for the measurement of ultra-sonic velocity with the highest precision.

The advantages of our new methods will be discussed elsewhere shortly.

The Mechanism of the Kolbe Reaction

IT has been observed by us that a variety of substances which are good catalysts for the decomposition of hydrogen peroxide produce a marked deviation of the anodic processes occurring during the electrolytic oxidation of thiosulphate[1] and of sulphite[2], and in the liberation of halogens[3]. We have now found that in the electrolysis of acetate solutions, relatively small amounts of plumbous, manganous, cupric, ferrous or cobaltous ions have a profound influence on the course of the Kolbe reaction For example, the addition of 0 001 *M*-lead acetate to a solution containing *N*-potassium acetate and *N*-acetic acid reduces the efficiency for ethane formation at a platinum anode from about 70 per cent almost to zero, when using a current density of 0·025 amp. per sq cm.

The effects of the ions mentioned are in the order Pb˙>Mn >Cu >Co = Fe , and an independent consideration of their catalytic influence on the decomposition of hydrogen peroxide, under the conditions prevailing at the anode during the electrolysis of an acetate solution containing acetic acid, has led us to arrange these ions into the groups (Pb , Mn) > (Cu , Co , Fe) This parallelism suggests the possibility that hydrogen peroxide is the effective agent in the formation of ethane by the Kolbe reaction, just as it appears to be in the other anodic oxidation processes we have studied.

A comprehensive investigation of the mechanism of the Kolbe synthesis was commenced some time ago, but as a period is likely to elapse before the final conclusions are ready for publication, we consider it desirable to make a preliminary announcement of the important observations relating to the effect of catalysts for hydrogen peroxide decomposition

Possible Chemical Nature of Tobacco Mosaic Virus

IN a recent issue of NATURE[1] Barton-Wright and McBain give results of experiments on the precipitation of virus from infected tobacco juice The method they used was that of Vinson and Petre, which consists essentially of the precipitation of the protein and other materials from the plant juice with basic lead acetate and the subsequent removal of the virus by elution with potassium-hydrogen phosphate solution Barton-Wright found that if the mixed phosphate eluate be acidified to a *p*H of 5 (which means, in effect, the conversion of the alkaline to the acid phosphate, KH_2PO_4) and 2 volumes of acetone added, a precipitate is thrown down, which is partly colloidal and partly crystalline. The colloidal material is largely protein in nature and is rich in virus. The crystals also contain virus.

I have been working on similar lines for the past two years, and I am in agreement with Barton-Wright and McBain up to this point. Barton-Wright and McBain, however, claim that they have been able to purify the crystals by repeated recrystallisation until they contain no nitrogenous material but still contain virus, and that no crystalline material was formed from healthy juice similarly treated. My experience may be of interest in this connexion. I have determined the presence of virus in the crystals quantitatively as well as qualitatively, using the N. glutinosa method In the original crystals there is a small virus content and some protein. As the crystals are washed and reprecipitated, virus appears in the supernatant liquid, and at each recrystallisation the amount of virus in the crystals is reduced After repeated treatment the crystals still contain a little virus, much less than originally, and they still contain a trace of organic nitrogen on microanalysis Nitrogen-free virus-containing crystals have not been obtained. I have found no evidence that the crystals contain virus except as an impurity

That the crystals have no specific relation to the virus is easily demonstrable If the K_2HPO_4 eluate from healthy tobacco tissue be acidified as was that of the infected material and two volumes of acetone added, a crystalline as well as a colloidal precipitate is obtained, despite the statement of Barton-Wright and McBain The amount of this crystalline portion of the precipitate depends on the concentration of the phosphate solution used in the elution of either the healthy or the infected juice If an $M/1$ K_2HPO_4 solution be used, the precipitate of crystals is very large

It can readily be shown that the crystals are due to the presence of KH_2PO_4 by the fact that the addition of two volumes of acetone to one of $M/1$ KH_2PO_4 in aqueous solution results in a heavy white precipitate of rhombic crystals, indistinguishable in outline from those obtained in the experiments recorded above

Activity of Crystalline Preparations of Vitamin B_1

IN an important letter, Dr. van Veen[1] describes the isolation of a vitamin B_1 preparation from rice polishings more potent by rice bird tests than our own At the same time he mentions that his activity reaches 500,000 units per gm It is well to realise that some of our most potent specimens have shown this activity by pigeon test[2], so that a final judgment upon the question must await further work

In addition to the strong probability that most vitamin B_1 crystals contain inactive vitamin, we must reckon with the further complication of different analytical figures. Dr van Veen's new crystals have the same analytical figures as previously, whereas repeated work shows that analysis of our crystals differs significantly and constantly from his (and others) in several respects, for example, C 42 2 per cent instead of 40 7 per cent Hence active torulin (from baker's yeast) appears to be different from active oryzanin. At present these differences cannot be reconciled with the published results of X-ray analysis[3].

We acknowledge with gratitude a specimen of Dr. van Veen's B_1, which is now under test.

Refractive Indices of *l*-Ascorbic Acid

E. G. Cox[1] states that *l*-ascorbic acid is optically negative with $\alpha = 1·462$, $\beta = 1·68$, and $\gamma > 1·70$. We have examined a material isolated from peppers after the method of A. Szent-Gyorgyi[2] by Dr. A. G. Grollmann, of the Johns Hopkins Medical School. This substance gives the characteristic absorption spectrum of *l*-ascorbic acid with a maximum coefficient[3] at 2650 A., the melting point is 188°, and the analysis (Mrs. M. S. Sherman) C, 40·80 per cent, H, 4·78 per cent (calculated for $C_6H_8O_6$, C, 40·89 per cent, H, 4·58 per cent). The compound as crystallised from methyl alcohol or acetone has $\alpha = 1·465$, $\beta = 1·600 \pm 0·006$, and $\gamma = 1·747$ for λ 5780 A. The optical sign is either positive or negative within the limit of experimental error, as is verified by the lack of curvature of the isogyre in a centred optic axis interference figure. No evidence was found for structural polymorphism, but the possibility was not rigorously eliminated. These constants, which are for crystals of the type shown in Szent Györgyi's Fig. 2a[2], are published since they are of value in identification of ascorbic acid and since they substantiate Cox's deduction of a plane configuration for the molecule, which is in accord with the accepted furanose ring structure.

Uroflavin, Maltoflavin and Redox-Potentials of Lyochromes

BESIDES hepatoflavin, the isolation of which was described in these columns recently[1], two further members of the lyochrome series have been obtained in a highly purified, though not definitely pure and crystalline state: uroflavin from normal human urine* and maltoflavin from malted barley. The process of preparation is very similar to the procedure adopted for the isolation of hepatoflavin.

Uroflavin as well as maltoflavin exhibit much the same properties as the lyochromes previously described. The yellow-red solutions show a strong green fluorescence. Whereas earlier observations with nickel oxide glass filters suggested that the fluorescence of lyochromes is mainly due to ultra-violet light, it was found by the use of a quartz monochromator that visible light of the blue-violet region and not ultra-violet radiation is responsible for the fluorescence. Both lyochromes yield chloroform soluble 'lumi-flavins' on strong irradiation in alkaline solution. Finally, both pigments lose their colour and fluorescence on reduction and regain these characteristics after reoxidation. The spectrographic examination, for which I am much indebted to Dr. E. R. Holiday, showed that maltoflavin and also uroflavin possess a sharp absorption band in the ultra-violet, the peaks of the band being at 255 mμ and at 281mμ respectively. In contrast to other lyochromes, there seems to be no specific absorption in the range of longer wave-lengths. The absorption curve of hepatoflavin shows two maxima, a sharp one at 258mμ and a flat one around 360mμ.

The potentiometric study of the three lyochromes proves that they represent perfectly stable oxidation-reduction systems. Even in low concentration they impart stable and fairly reproducible potentials to noble metal electrodes within the range of a reasonable redox buffering capacity. As reductants hydrosulphite or palladium-hydrogen, and as oxidants ferricyanide or molecular oxygen, were used. The position of the normal potentials (E'_0, referring to the normal hydrogen electrode) was found as follows: Hepatoflavin: *p*H 5·88, $E'_0 = -0·177$ v.; *p*H 7·3, $E'_0 = -0·219$ v.; *p*H 8·62, $E'_0 = -0·274$ v. Maltoflavin: *p*H 7·4, $E'_0 = -0·216$ v. Uroflavin: *p*H 7·2, $E'_0 = -0·217$ v. (phosphate buffer of isotonic strength was used throughout). The titration experiments were performed at room temperature (16°–19·5° on different days, constant within 1° during the experiments). The curves obtained so far indicate an electron number of $n = 1$ rather than of $n = 2$. It should be mentioned that Bierich *et al.*[3], working with a product from mammalian tissues which is probably identical with lumi-flavin[1], report an E'_0 of $-0·217$ v. at *p*H 7·2 and of $-0·139$ v. at *p*H 5·39, but give index potentials corresponding to $n = 2$.

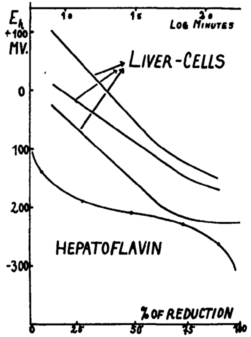

FIG. 1.

The physiological significance of the extremely negative position of the normal potentials of these widely distributed biological redox-systems awaits elucidation. Under normal aerobic conditions, if there is such a state as a uniform aerobic reduction potential (which would then be near to $r_H = 12$)[4], the cell flavin would be present entirely in the oxidised state. But around $r_H = 7$ ($E_h = -200$ mv.), which is considered to be the general anaerobic reduction potential of living cells, the cell flavin is exactly in its equilibrium range. This fact is illustrated in Fig. 1, which in its upper part shows an experiment of Clark *et al.*[5], in which the reduction potential of liver suspensions in phosphate buffer at *p*H 7·4 was observed, whilst in the lower part one of our curves obtained on reduction of hepatoflavin at pH 7 3 is given.

---

* Uroflavin is a component of the urochrome fraction, but not identical with urochrome *A* or *B* (cf. [2]).

Another striking coincidence is represented by the fact that the normal potential of the lactate-pyruvate-enzyme system[6] is almost identical with the normal potential of the flavins at the same pH (E'_0 being respectively -200 mv and -219 mv (hepatoflavin) at pH 7) The relation between the flavin potential and the equilibrium conditions in enzyme-substrate systems is under investigation

A Camera Method for Charting Quadrats

THE botanical analysis of pastures by means of quadrats should combine both speed and accuracy Up to the present, the rapid methods have been somewhat subjective, and in many cases the results obtained cannot be compared closely owing to variation in the personal factor The more intensive objective analyses, on the other hand, have sacrificed speed to greater accuracy The following method of quadrat charting has accordingly been devised in order to secure both speed and accuracy, and is of special value in the charting of open tufted swards such as those commonly found in South Africa

The apparatus consists of a wooden square metre quadrat to which is screwed a tressel with an extra leg at each end to secure rigidity. The precise form of this tressel is unimportant, that it should be rigid is all-important The tressel supports a camera directly over and focused towards the centre of the quadrat The image of the quadrat is thrown not on to the usual frosted focusing glass, but on to a *sheet of plain glass* upon which is secured a *sheet of transparent (or oiled) squared paper* The image of the vegetation within the quadrat can then be traced by pencil with ease and accuracy upon the paper

In using the apparatus, it is desirable to have two workers, one tracing the outline of the plants (basal cover or otherwise), the other moving the foliage of the grass, etc, to render the outlines clear to the tracer, and, if necessary, identifying the species For ease in working, the light-hood screening the image should fit closely to the top of the camera, and be provided with eye-pieces and an arm-hole at the side Both vertical and lateral adjustments of the camera are provided for on the frame, but once the correct position is obtained no further adustments are necessary

The method has several advantages

(1) The apparatus is readily constructed from simple material Any half-plate camera can be employed, provided it has a suitable wide-angle short focus lens (approximately 5 4).

(2) The apparatus is collapsible and can be fastened into a small bundle for moving long distances; for short distances, the whole apparatus when set up can be moved with ease.

(3) Once adjusted, no further adjustments are necessary

(4) Photographs of the charted vegetation may be obtained if necessary by merely substituting the dark slide for the glass plate.

(5) It is both rapid and accurate in use A tufted sward, composed of a number of different species, can be charted and identified in ten to fifteen minutes

Diethyl Peroxide as a Pro-Knock

IN spite of the considerable literature, there seems to be no special reference[1] to the properties of diethyl peroxide as a pro-knock In view of its possible importance in some theories of hydrocarbon combustion, it was of interest to investigate its behaviour in the engine Diethyl peroxide is a violent pro-knock, slightly more potent than amyl nitrite at the same concentration Its knocking action is inhibited by lead ethyl

Ethyl hydrogen peroxide is likewise definitely a pro-knock In spite of the ease of thermal decomposition, 30 per cent of hydrogen peroxide was found to have definite, but very slight, pro knock tendency

Apart from the possible theoretical significance of these facts, which is being discussed elsewhere, it seems desirable to record the pronounced knocking behaviour of this class of compounds

Three Discharges of Ball Lightning

At 4 15 p m on January 11, the phenomenon of ball lightning occurred at the house of Mr Joseph M. Wreath, Ballymoney, Co Antrim

A first ball exploded against the corner of a metal-bound tea chest just inside the wide open door of a coach-house in a walled-in yard attached to the dwelling-house A second exploded a minute or two later against a ladder leaning against the same coach-house A third entered a ground floor room of the dwelling-house, having come down the chimney against the up draught due to a fire burning at the time It exploded in the fireplace.

The balls outside were seen by Mr. Wreath and a friend, who describe them as orange-red and as being of about the size and having the velocity of a cricket ball That indoors was seen by two ladies

A wireless aerial is attached to the chimney stack by which the third ball entered the dwelling-house

Research Items

Mohenjo-daro. The Sir George Birdwood memorial lecture of the Royal Society of Arts delivered on December 8 by Dr. E. H. J. Mackay (see NATURE, 132, 960, Dec. 23, 1933) is published in full in the Society's *Journal* of January 5. The objective of the six years' excavation under Dr. Mackay from 1927 to 1933 was to establish the cultural history of the city in the period represented by the lower strata. Attempts were made to reach virgin soil, but these had to be abandoned at a depth of 43 ft. below the surface of the mound owing to the seepage of water from the Indus. The earliest remains of the city must be regarded as irretrievably lost, failing the employment of expensive pumping operations. The city from the earliest times was laid out in rectangular blocks of remarkable accuracy, the streets running at right angles. Excavations have been carried down to six levels of occupation, the finest and most carefully laid masonry being found in the early levels. Houses were well built up to the end of the Intermediate Period, when signs of economy appear and walls were made thinner. Houses were of two or more stories, the upper being reached by brick staircases. The drainage system is the most elaborate of any city of the same date even outside India. In the last two phases, when the wealthier population had left the city owing to floods, houses were roughly built and those of the *DK* mound were occupied by artisans. The city at this time was apparently exposed to raids from hill tribes, as skeletal remains have been found of inhabitants who had suffered a sudden and violent death. The skulls fall into two classes, Mediterranean and proto-Australoid, one showing a Mongolian strain. Cultural affinities with Mesopotamia, the results of trade, point to a date 2750–2500 B.C. for later strata and about three hundred years earlier for the lower levels. The highest art of the people is shown in the cutting of seals, the subjects affording valuable evidence of their religious beliefs. They appear to have been of western Asiatic origin, but there is at present nothing to indicate the date or route of their entry into India.

Jungle-Fowls from the Pacific Islands. The origin of the jungle-fowls of Polynesia, whether from wild individuals imported from Asia or from varieties already domesticated, is uncertain; but, on the whole, the probability lies with the former suggestion. If that be so, then the great variety of the Pacific races, now living in a feral state, must be due to changes which have taken place since the introduction of the wild species, probably long before Wallis and Cook discovered the natives of the Tuamotus and Tahiti using the birds for food, in 1767 and 1769. Stanley C. Ball, in a monograph of the Pacific Islands forms, points out that, compared with the wild *Gallus gallus*, they are on the average considerably larger, and their variation in size greater (*Bull. Bernice P. Bishop Museum*, 108; 1933). Variation appears to have been greater in the Society and Marquesas archipelagos than in Fiji and the New Hebrides. In the western groups, white spotting is the single remarkable variation, whereas the Marquesas has a red strain with feathered tarsi and yellow-backed males, and in the Society Islands, white-backed males, melanic cocks and hens, white-laced hackles, mingle with the wild type. But all the birds, everywhere, are single-combed.

Scottish Tunicates. Dr. Harold Thompson continues his studies of tunicates in his paper "The Tunicates of the Scottish Area, their Classification, Distribution and Ecology. Part 3. Sedentary Tunicata (continued) Order Diktyobranchia" (Fishery Board for Scotland. Sci. Invest. 1932. No. 2, 1933). Mainly based on records from Scotland, the work represents a thorough overhauling of the groups dealt with, which in the present part include the Rhodosomatidæ, Ascidiidæ, Perophoridæ and Cionidæ. In a paper by Lindsay and Thompson (*J. Mar. Biol. Ass.*, 17, 1, 1930) the author has already inquired into the determination of specific characters in the family Ascidiidæ, in which it was suggested that the three recognised genera *Phallusia*, *Ascidia* and *Ascidiella* of Roule might be combined. In the present paper the same combination is kept, and with the genus *Ascidia* are merged both *Ascidiella* and *Phallusia*. There is a very large list of new Scottish records given for *Ascidia scabra* as distinct from *A. aspersa*. Within the order Diktyobranchia there are two species typical of arctic conditions, two of arctic and north boreal conditions, eight typical of boreal conditions and two of south boreal conditions. The boreal species tend to be confined to the Mediterranean and east Atlantic boreal regions, and, with the exception of *Ascidia scabra*, *Ciona intestinalis* and to some extent *Ascidia virginea* and *Ascidia conchilega*, tend to fail in North Sea water proper.

Tidal Bores. In the *Geophysical Supplement* (vol. 3, No. 5) to the *Monthly Notices of the Royal Astronomical Society*, Dr. Vaughan Cornish describes observations made by him on tidal bores on the Severn and Trent. The paper is non-mathematical, but the observations are quantitative, and made with the view of providing data on which can be based an adequate mathematical investigation of the type of bore most characteristic of English and French rivers. In this type the steep slope of the head of the tide breaks up into a group of short waves. In his observations on the Trent, during the years 1922–28, Dr. Cornish observed the same bore at different points up the river, travelling from point to point by motor-car, outstripping the bore. He observed not only the changes in form of the bores when rounding bends, and across points where the river depth changed rapidly, but also in passing the mouth of a canal opening on to the Trent. He urges the need of a co-operative study of the Trent bore, by a group of students equipped with tide-gauges, current meters and kinematographic cameras.

Low Temperatures by Adiabatic Demagnetisation. De Haas, Wiersma and Kramers describe (*Physica*, 1, Dec. 1, 1933) the experiments which have led to the lowest temperatures yet attained. A quantity of a paramagnetic salt is cooled by liquid helium and kept for some time in the field of a large electromagnet. The field is then suddenly reduced, and the demagnetisation of the salt under approximately adiabatic conditions causes its temperature to fall. The specimen is arranged to lie in an inhomogeneous magnetic field and the mechanical force on the specimen is measured by a balance, so that its susceptibility may be determined. The magnetic susceptibility is used to provide a scale of temperature which is extrapolated below the temperatures measured with liquid helium. The salts used were cerium fluoride and the ethylsulphates of cerium and dysprosium. In an experiment recorded in a footnote potassium chrome alum was used, and gave the lowest temperature—below 0·05° K. (see also NATURE, 132, 372, Sept. 9, 1933).

Oxidation and Condensation of Phenols. The *Proceedings of the Royal Society* of December contains a set of papers by H. G. H. Erdtman on the oxidation and condensation products of phenols. It seems probable that the complicated substances called 'humic acids' possess an aromatic structure and that they are produced by the coupling of quinonoid molecules. The first part of Erdtman's work is the investigation of the reactivity of some simple monocyclic quinones in the light of Lapworth and Robinson's application of the electron theory of valency. According to this theory, the reactivity of unsaturated molecules may be explained in terms of the 'polarisation' of parts of the structure. The reaction studied experimentally was the acetylation of the quinines with a mixture of acetic anhydride and sulphuric acid, and the reactivity of the various quinones showed a fairly good agreement with the predictions of the theory. The theory also suggests a mechanism for the coupling of carbocyclic rings during the oxidation (dehydrogenation) of phenols. A typical example is the formation of a hexahydroxydiphenyl on the oxidation of pyrogallol in baryta solution, and a whole series of such couplings was investigated. During the work, an investigation of the polymerisation of toluquinine led to the discovery of a termolecular condensation product, and a termolecular product was also obtained from benzoquinine, though in this case further polymerisation leads to a poor yield; α-naphthaquinone yields more crystalline termolecular product than toluquinine.

Medieval Glass. Very little information is available on the chemical composition of medieval glass, although this is obviously an important criterion of the genuine nature of particular specimens. A detailed account by M. Chesneau (*Bull. Soc. d'Encouragement pour l'Industrie Nationale*, 132, 609; 1933) of the chemical analyses of French window glasses of the twelfth and thirteenth centuries is therefore of considerable interest. These glasses contain less silica and more alkali (potash and soda) and alkaline earths (lime and magnesia) than modern glass, the mean percentages being 70 per cent silica, 17 of alkali (soda) and 13 of lime, and are therefore more fusible and more easily attacked by moisture and atmospheric carbon dioxide, although the actual specimens were well preserved. The addition of common salt during fusion, as mentioned by Agricola, is considered probable, since the proportion of soda to potash in the glasses is larger than could be accounted for by the use of wood ashes alone, as specified by Theophilus. The probable method of working is fully described, the glass being first blown, and the pear either pierced and spun or worked into a cylinder, afterwards cut and opened out. The glass had been decolourised by addition of pyrolusite and the colours were due to metallic oxides, the red glass, however, being formed by a thin sheet of red superposed on or interposed between colourless glass. The red was coloured with cuprous oxide; the blue with cobalt with traces of cupric oxide and having a grey tone owing to the presence of nickel; the yellow contained antimony oxysulphide with some ferric oxide; the violet had oxide of manganese (pyrolusite) together with some ferric oxide, giving the flesh tint of all ancient violet glasses; and the green contained cupric oxide. The cobalt mineral in all probability came from Saxony, the other minerals being native in France.

Transient Waves on Transmission Lines. The importance of preserving the best possible continuity of supply on electric transmission lines has led engineers to study the effects produced on them by transient or 'travelling wave' phenomena. A great many experimental and theoretical researches particularly in the United States have now been published on this subject. The waves are caused mainly by lightning, but sometimes a fault connecting the line to the earth by an arc, or even switching operations will cause them. In a paper read to the Institution of Electrical Engineers on January 4 by Dr. J. L. Miller, the influence of these waves on electrical devices is discussed. Dr. Miller states that lightning is practically always the cause of dangerous over voltages. American experimenters have shown that lightning surges can cause a pressure rise of about seven or eight times the normal voltage. In one particular case careful records were kept of the disturbances occurring on five different transmission lines over a period of five years. It was found that one per cent reached fifteen times normal line voltage, five per cent reached eleven times normal line voltage and ten per cent reached eight times this voltage. Altogether, nearly 700 surges were recorded and 73 of them were more than eight times normal. It is concluded that a line at the British grid pressure of 132 kilovolts would, if placed in this district, be liable to three surges per annum of the order of a million kilovolts. It will be seen that transformers and other electric devices would have to operate under dangerous conditions. An oscillogram has been obtained which shows a surge which rose to five million volts in less than two microseconds. The author gives a fairly complete mathematical theory and checks it by showing high-speed cathode ray oscillograms of the phenomena. He has explored a very wide field about which opinion is still divided.

The Support of the Chromosphere. A novel theory of the manner in which the chromosphere is supported has been put forward by Dr. S. Chandrasekhar (*Mon. Not. R.A.S.*, 94, No. 1, November 1933). The difficulty of accounting for the enormous extension of the chromosphere was first met by Prof. E. A. Milne, who suggested that the calcium atoms were supported by selective radiation pressure. It has also been suggested that turbulence is a cause of the behaviour of the chromosphere. Dr. Chandrasekhar has extended Milne's theory in a very interesting way. Guided by the observed granular appearance of the solar disc, he discards the notion of hydrostatic equilibrium, and introduces instead the hypothesis that the chromosphere is in a hydrodynamically steady state. The mean flux of radiation corresponds to full support of the chromosphere, and atoms over bright areas are accelerated outwards, while those over the darker patches tend to fall back. The theory predicts for the outward march of the density gradient a law which keeps numerically close to an exponential law.

Elementary Science in Secondary Schools

IN a consideration of the School Certificate Examination, the Panel of Investigators appointed by the Secondary School Examinations Council reported in 1932* that so far as science is concerned, the examination was unsatisfactory. There are fifteen possible ways that a candidate for School Certificate may be examined in science, no examining body having less than five possibilities. By taking advantage of the possibilities offered, a candidate may under some examining bodies offer for a science pass in School Certificate, either heat, light and sound, or magnetism and electricity, without any other science subject. While this is possible in only three out of the eight examining bodies, in all cases a candidate need only offer one science, usually chemistry, physics or botany, in order to pass in science. The concentration thus demanded on a single science subject in the school examination is not regarded as in the best interests of the pupil or of science, in that it is impossible to achieve any satisfactory training in scientific method by a consideration of any one single science, and that also such a procedure does not give to the pupil a sufficiently comprehensive idea of what is connoted by the term 'science'.

These disadvantages, to which the Panel of Investigation directed attention, have been realised by some examining bodies, and attempts have been made to suggest broader conceptions of science in examinational syllabuses. Thus general physics, physics cum chemistry (under various names), biology, and general science have been introduced as alternative papers. The general physics paper is a purely qualitative paper, covering superficially almost the same ground as the normal physics paper, the physics cum chemistry paper is usually resolvable into a 'test on a little chemistry plus a truncated course in physics"; the biology, while obviously a better introduction to life sciences than either the single subjects of botany or zoology, is usually tested by a paper divided into two sections, one botanical and the other zoological, "with little to suggest that the paper is dealing with the phenomena of living things as a whole". The most successful has been the general science paper, which, however, has been subjected to the criticism of superficiality.

These particular criticisms are made by the Investigators as a corollary to their general criticism of the connexion between School Certificate and Matriculation. The original intentions† of the School Certificate Examination were to "test the results of the course of general education", and to be suitable for forms in which the average age of the pupils ranges from about 16 years to 16 years 8 months, and that "the standard for a pass will be such as may be expected from pupils of reasonable industry and ordinary intelligence in an efficient secondary school", and it was only intended secondarily to act as a qualifying examination for entrance to universities. There is no doubt, however, that these original intentions have become obscured, and the university entrance qualification has become predominant, Matriculation being regarded as a superior kind of School Certificate by both candidates and employers. The Investigators note the number of students entering universities from State-aided secondary schools in England and Wales in 1930–31 as 4,132, whereas the number of candidates who qualified for matriculation in the School Certificate examinations conducted by London and the Northern Joint Board in July and December, 1931, was 11,119; in other words, considering all possibilities, not more than one in four of the pupils in State-aided schools who "matriculate actually proceed to a University". Hence arises the much condemned university domination of the secondary school curriculum.

These lines of criticism of the secondary school examinations agree with the new tendency of the secondary school to regard its pupils as potential citizens and laymen, and not necessarily as potential specialists in science or any other subject. In other words, the modern secondary school is beginning to face towards the practical world of the ordinary citizen and away from the necessarily narrow academicism of the university specialist. The secondary school curriculum is being recast to bring it in line with the requirements of intelligent laymen living in a modern world.

This broadening tendency is making itself most manifest in the school science syllabuses. Thus it was agreed at the annual meeting of the Science Masters' Association on January 4 "That there is a general body of scientific knowledge not confined to either of the special fields of the physical and biological science which ought to be known both by the ordinary citizen and by those who may ultimately specialise in some corner of one of those two fields". This broader aspect of science is being termed 'Elementary Science' in order to avoid confusion with existing syllabuses designated 'General Science' and 'General Elementary Science', which, although an approach in the required direction, suffer from certain defects, criticisms, and traditions that it is hoped 'Elementary Science' may avoid.

A sub-committee of the Science Masters' Association in a recent report, defines 'Elementary Science' as "a method of presenting the fundamental principles of science based on the interpretation to youth of the world in which he lives, involving not only an understanding of those fundamental principles, but also of the attitude and method of science generally. Science is here regarded as a living whole, comprehending all the sectional sciences necessary to give youth an intelligent understanding of his biological, chemical and physical surroundings".

It is emphasised that the value of such science to the pupil lies not only in a wide appreciation of his biological, chemical and physical environment, but also in an understanding of the characteristic attitude and methods of the scientific worker. Moreover, 'Elementary Science' places the needs of the pupils before the demands of any sectional science, its essence lies not so much in the syllabus, the content of which must be selected and organised according to the actual environment and needs of the pupils, as in the interpretation of it as a method of explaining that environment. Its content must, of course, include the three fundamental sciences of biology, chemistry and physics, but the proportions of each are determined not by their relative importance as sciences, but by the extent to which they each contribute to the environment

---

* The School Certificate Examination. (H.M. Stationery Office, 1932.) See NATURE, 131, 217, Feb. 18, 1933.

† Board of Education Circular 849 and subsequent circulars.

In order to meet the criticism of superficiality and triviality to which all broad schemes of science teaching are subject, the sub-committee referred to has drawn up not only a suggested syllabus, but also a list of fundamental principles of science, the application of which is of fundamental importance in the life of the ordinary citizen, and towards a knowledge of which it is felt that any course of elementary science, whatever its content, should aim These fundamental principles presented as the aims of the new subject need, and it is hoped will get, criticism and correction by scientific workers, laymen and all interested in educational matters

It is realised, too, that there are many practical difficulties of method, organisation and teaching, particularly where teachers are by their training of necessity specialists, but it is felt that with a clear statement of aim and policy, these difficulties will not be insuperable.

What is more controversial is the recommendation of the Investigators, which was agreed to by the Science Masters' Association at the annual general meeting, to make an examination in this subject of elementary science compulsory for all School Certificate candidates, unless they offer all three science subjects, biology, chemistry, physics But it is felt that, while no brief is held for examinations, as such, so long as they exist they do largely influence the curriculum of the schools, and unless the subject of elementary science, like English and mathematics, is made compulsory, it will not receive serious consideration in competition with other subjects of examinational value Moreover, much as compulsion is disliked, it is pointed out that compulsion for the science candidate virtually exists at the moment, but confined to a very narrow field of one science, or part of one science The result of the adoption of compulsory elementary science in School Certificate would broaden both the examination and the school curriculum and thus be of most benefit to what, after all, should be the paramount consideration—the needs of the ordinary pupil F W TURNER.

Patents and Inventions

THE Institution of Mechanical Engineers has recently formed an Inventions Advisory Committee with Mr W Taylor as chairman In connexion with the inauguration of this Committee, on January 26 a meeting of the Institution was held when four short papers were read dealing with invention and inventors These papers were "The Evolution of Invention", by H. W. Dickinson, "The Inventor", by Dr H S Hatfield, "Provisional Patent Protection and Patent Claims", by Sir William Jarratt and "The Development and Exploitation of Inventions", by A H. Gledhill.

The subject is a vast one, for as Mr Dickinson said, "All social, economic, physical, technical, and commercial developments are the result of invention, and we may say that civilization is a synthesis of the inventions made by man since his appearance on this planet a million years ago" The word invention to day has three meanings · (1) the thing schemed or contrived, (2) the mental processes involved, and (3) the ability to evolve the new scheme or contrivance, commonly called inventiveness As regards the encouragement of invention, England furnishes the first known instance of encouragement being given to the producer of a new process, for in 1440 (18, Henry VI) Letters Patent were granted by the Crown to John of Schiedam and his company for a method or process of manufacturing salt. It was, however, the Statue of Monopolies of 1624 which formed the basis of our present patent systems

Dr Hatfield seems to consider the technical inventor to be a new figure in the history of mankind, but it is doubtful whether this view is correct The ships, the aqueducts, the tunnels and the buildings of the Romans were the result of the accumulated inventions of the day, and these would have undoubtedly been followed by others had not the Empire been overwhelmed by the barbarians of the north In concluding his contribution to the symposium, Dr Hatfield attempted to define the mental characteristics which distinguish the successful inventor.

While the papers of Mr Dickinson and Dr Hatfield referred largely to the philosophy of invention, those by Sir William Jarratt and Mr. Gledhill discussed the position of the inventor and of patent legislation to-day Sir William Jarratt congratulated the Institution on the formation of a Standing Committee to consider inventions submitted by members Some years ago, he said, he served on a committee appointed to consider the best method of dealing with inventions made by Government servants, and through the report of that committee each of the great Departments of State has now an Awards Committee, with power to recommend monetary awards for inventors If industry in Great Britain is to maintain and improve its position in the world, it will be necessary that discovery and invention shall continue to be encouraged by public and private benevolence, by research scholarships, by a sound system of patents and by the work of committees such as that of the Institution of Mechanical Engineers

The last paper, that by Mr Gledhill, dealt concisely with the commercial development of inventions, the sale of the products of an invention and the manufacturing of the product of an invention Incidentally, he mentioned that the Patent Office made a net profit of £146,000 last year, and he suggested that a portion of this might wisely be used to encourage developments of inventions which would benefit the country. It might also be proposed that some of this profit be used to improve the conditions under which the examiners work and for the upkeep of the library, where many books are in need of rebinding and where a system of vacuum cleaning would be advantageous. It may indeed be doubted whether an increase in the facilities for inventors and a reduction of their fees is not a sounder national policy than to look to the Patent Office as a source of revenue

That there is a need for a continual revision of the patent laws was suggested by several of those who took part in the discussion of the papers The general interest shown in the discussion is a good augury for a new departure of the Institution, which as the chairman, Col A E. Davidson, said, is justified by its Royal Charter, which states that one object of the Institution is "to encourage invention and research in matters connected with mechanical engineering"

The Piezo-Electric Loud-Speaker

MODERN broadcasting receivers tend to give an undue response to the lower audio frequencies, and in the majority of cases the range is limited to frequencies below 5,000 cycles per second. This is partly due to the fact that the lower frequencies, which at one time were not reproduced very well, have now become attractive as lending power and tone to the reproduction, but it is also due to the demand for increased range in distant reception, for which purpose a high selectivity is required, a virtue which is most easily attained by reducing or eliminating the higher frequencies. Compensation for this latter deficiency can be obtained to some extent by using tone correcting arrangements in the audio-frequency stages of the receiver, but the effect of these in the sound reproduction is rather handicapped by the poor response of the moving-coil type of loud-speaker to the higher audio frequencies.

A solution of this difficulty is now in view in the form of the piezo-electric loud-speaker, an investigation of which has been described in a paper by Stuart Ballantine, of the Boonton Research Corporation, U.S.A., published in the *Proceedings of the Institute of Radio Engineers* of October 1933. The loud-speaker employed in these measurements was of the horn type and was driven by a piezo-electrically active diaphragm built up of crystals of Rochelle salt (sodium potassium tartrate), prepared by the Brush Development Company of Cleveland, Ohio. The diaphragm is formed of four pairs of crystal plates, the plates of each pair being so cut that they move in opposite directions under the influence of an electromotive force. The opposite faces of such a pair of plates are cemented together, and the combination, when clamped along one edge, tends to twist on the application of a potential difference to its foil electrodes. Four such units are cemented together to form a flat square diaphragm, which is clamped around its periphery, so that in use the centre portion or junction of the four units vibrates normally to the plane of the assembly, and in synchronism with the audio frequency electromotive force applied to the metal foil electrodes.

The characteristic of this type of loud-speaker, that is, the relation of output sound pressure to frequency, can be controlled to some extent by the electrical circuit in which it is used and also by the resonant frequency of the crystal diaphragm, which depends upon its dimensions. In an example illustrated in the above paper, the sound pressure rises fairly uniformly with frequency from about 1,000 cycles per second to the resonant value at 8,000 cycles per second. This characteristic may be partially levelled off by suitably connecting it to an electrical circuit, and in a second case in which the loud-speaker was fed through a transformer in series with an inductance, the sound output, after increasing rapidly between frequencies of 1,000 and 2,000 cycles per second, remained sensibly uniform for higher frequencies up to 10,000 cycles per second. This type of response immediately suggests the possibilities of a combination of a piezo-electric loud-speaker with one of the moving-coil type, in which the output is moderately constant for low frequencies but falls rapidly above the cut-off frequency. Ballantine describes such a combination using a moving-coil loud-speaker which has been designed for uniform reproduction up to 3,000 cycles per second, with a rapidly falling response above that frequency. The combined output is shown to be approximately uniform at all frequencies between 60 and 9,000 cycles per second. Such dual arrangements have the advantage that the response can be limited to that of the low-frequency member of the pair if considerations of noise or transmission interference make this desirable.

The piezo-electric loud-speaker also forms the subject of an article in the *Wireless World* of January 5, in which the development in Great Britain, by the Rothermel Corporation Ltd., is briefly described and illustrated. In this case the crystal unit is built up of four laminations, approximately 2½ in. square, the total thickness being ¼ in. Three of the corners of this assembly are clamped between rubber blocks, and the vibration of the fourth corner is used to drive the cone diaphragm. The equivalent capacity of this unit is of the order of 0·03 mfd., and it is suitable for use in conjunction with an ordinary moving-coil output transformer. The efficiency of the unit appears to be very good, particularly in the frequency range 2,000–8,000 cycles per second, while in combination with a standard type of permanent moving-coil loud-speaker the quality of reproduction is claimed to be superior to that hitherto obtained with commercial dual moving-coil units.

Larval Crabs from Japan[*]

DR. HIROAKI AIKAWA has recently supplemented his first paper on the newly-hatched crab zoeas of Japan (1929) with one on the intermediate (later zoeal) stages between the first zoea and the megalopa. Crab zoeas of all kinds are very common in the Japanese plankton, but few of them have been traced to the adults, and the author has devised a distinctly helpful scheme for placing them in groups characterised by definite features. Recent research by other workers has shown that there are several larval characters by means of which the various natural divisions can be recognised; the Oxyrhyncha can be divided from the Brachyrhyncha and many of the families and genera can be identified, whilst by rearing the individuals several species are now known throughout the whole life-history. The Dromiacea always stand apart and should certainly be separated from the Brachyura.

The most important features which can be used in classification are the number of spines on the carapace, the form of the antennæ and the number and position of the spines on the telson. Dr. Aikawa uses the position on the body of the main chromatophores, but these are no good in long-preserved material. Besides elaborating the classification of the antennæ and telson, he now adds the establishment of a hair formula for the endopodite of the two maxillæ and of the second maxillipede and of the joints of the latter, which he finds are constant for the species through all the zoeal stages. He has established nine groups of zoeas based on the form of the antennæ and telson by the aid of which any unknown zoea of any stage may be classified approximately, but the classification is admittedly not a natural one For example, the group Inachizoea is typical for the Inachidæ, but also contains *Pilumnus*, *Heteropanope* and *Gonoplax*, whilst the group Grapsizoea, although one type is chiefly confined to the grapsoid crabs, contains another type in which are included many of the Portunidæ, also *Thia*, *Eriphia*, *Hyas* and *Maia* , nevertheless, with the further and more exact descriptions of the individual zoeas, one can get a very good idea of their probable position in a natural classification and comparing it with those the adults of which are known, many genera can already be identified

---

[*] *Records of Oceanographic Works in Japan*, 5, No. 2, June 1933. "On Larval Forms of Some Brachyura". (2) "A Note on Indeterminable Zoeas", by Hiroaki Aikawa.

The system of groups here given is to be regarded as a kind of key which is really helpful and a distinct step forward in the elucidation of the difficult brachyuran larvæ Several zoeas are described and figured, none of which can be actually referred to any known species, but they are classified into these groups It is possible, however, from the characters given to place them at least in the families if not in the genera to which they belong.

It is hoped that in the near future the author will produce a similar grouping for the megalopæ, which is much wanted

University and Educational Intelligence

CAMBRIDGE —Prof Werner Heisenberg, of the University of Leipzig and Magdalen College, Oxford, has been appointed Rouse Ball lecturer for the year 1933–34.

At Queens' College, Prof James B. Buxton, professor of animal pathology in the University, has been elected to a professorial fellowship

LONDON —The University is making a grant of £100 towards the fund for the purchase of the "Codex Sinaiticus"

A course of six lectures on cytology will be given at University College, Gower Street, London, W C.1, on Wednesdays commencing on February 7, at 5 p m by Dr R J Ludford, Dr E. S. Horning and Dr K C. Richardson. The lectures are open to the public.

OXFORD —On Tuesday, January 23, Congregation approved an amending Statute for defining more exactly the scope of the Hope professorship of zoology, by adding ("Entomology") to the designation of the professorship, and to the mention of "zoology" wherever it occurs in the statement of the professor's duties

At the same meeting of Congregation, the Master of Balliol, in moving the preamble of a statute for extending and improving the provisions for the study of forestry in the University, directed attention to the fact that the clauses of the statute, if they were deemed unacceptable, were open to revision by amendment at a later stage. The same point was urged by Dr. N. V. Sidgwick. Prof. F. A. Lindemann, though refraining from opposing the passing of the preamble, thought that the statute in its present form provided no sufficient guarantee for ensuring the permanence of grants. The preamble was carried without a division.

Prof. W. G Le Gros Clark, professor of anatomy at St Thomas's Hospital Medical School, University of London, has been appointed Dr. Lee's professor of anatomy

On Tuesday, January 30, Congregation approved the preamble of a statute establishing a statutory readership in physical anthropology. The Senior Proctor, Mr H. G Hanbury, of Lincoln College, explained that the duties of the post had been voluntarily undertaken by the former Lee's professor of anatomy , and that the present measure was called for in consequence of the recent retirement of Dr Arthur Thomson from the professorship

The honorary degree of M A was conferred on Miss Ethel Bellamy in recognition of her work at the University Observatory on the photographic chart of the heavens

Science News a Century Ago

The King's Speech, 1834

February 4, 1834, saw the opening of Parliament, and amongst the items dealt with in the Speech from the Throne (Earl Grey, Prime Minister) was a mention of the Act passed in the previous session abolishing slavery under the British flag Legislation dealing with the status and power of municipal corporations was forecast (but was not passed until 1835) The Speech lamented the continued distress amongst the proprietors and occupiers of land, and Parliament was recommended to give early consideration to such a final adjustment of the tithes as may extinguish all just causes of complaint On the subject of Ireland the Speech contained the following passage "But I have seen with feelings of deep regret and just indignation the continuance of attempts to excite the people of that country to demand a repeal of the legislative union".

Porcupine Men

During January 1834, a middle-aged man, of very athletic and robust form of body, completely covered with a green horny substance in the form of quills, not dissimilar to those which are produced on the porcupine, presented himself at the Westminster Hospital for exhibition The parts which had escaped the deformity were his face, the palms of his hands and the soles of his feet , every other part of his person was abundantly supplied with this green horny substance He stated that he shed his horns, or quills, annually, and a fresh crop succeeded

A description of the case appears in the *London Medical and Surgical Journal* of February 6, 1834 The man was a member of the celebrated Lambert family, in which this remarkable condition, an extraordinarily scarce form of the skin disease named ichthyosis hystrix, was present in at least six generations. In every case the condition appeared about two months after birth and affected the males only The case of the first member of the Lambert family to be affected was reported to the Royal Society on March 16, 1731, by John Machin, the secretary, and Prof. Gresh (*Phil. Trans* , 38, 299 ; 1731) at fourteen years of age, and in 1755 at the age of thirty-eight with his son Edward by Baker (*ibid.*, 49, 21; 1755). Edward and his two sons, who all presented a similar skin condition, visited Germany and France, where they were described under the name of "Porcupine Men" by Blumenbach, Autenrieth and Tilesius. Other members of the family similarly affected were afterwards described by Elliotson in 1831, Pettigrew in 1834 (in the subject of this note) and by Pickells in 1851 Further details concerning the Lambert family, including a reproduction of the figure published in 1802 by Tilesius, will be found in E A Cockayne's "Inherited Anomalies of the Skin and its Appendages" (1933), pp 182–85, from which most of the above information is taken

The Franklin Institute

At the beginning of the nineteenth century, Philadelphia was the centre of scientific culture in the United States The American Philosophical Society had been founded in 1769, with Franklin as its first president, while in 1814 and 1824 respectively, the Academy of National Sciences of Philadelphia, and the Franklin Institute of Pennsylvania were inaugurated. The latter society had its birth at a meeting held in the County Court House on February 5, 1824, when it was resolved that "it is expedient to form a Society for the promotion of the useful arts in Philadelphia, by extending a knowledge of Mechanical Science to its members and others at a cheap rate" It was also resolved to attain this object by means of lectures, the formation of collections and of a library and the award of premiums for inventions The Institute held its first public exhibition in October 1824, its first hall was erected in 1825, and the following year the *Franklin Journal* was established Two years later this was renamed the *Journal of the Franklin Institute*, by which title it has since been known

From the first the *Journal* contained original contributions, reprints from other periodicals, reports of committees and notices of American inventions The annual report of the Board of Managers submitted in January 1834 was signed by Alex Dallas Bache At that time there were 1,659 members, and "the condition of the Institution was one well deserving mutual congratulations From a small beginning, in an attempt to diffuse useful knowledge, to promote practical science and the mechanic arts, the institution had grown to be respected by her members and the public" The report refers to courses of lectures by Prof J K Mitchell on chemistry, by Prof W R Johnson on natural philosophy and by Gouverneur Emerson, M D, on meteorology Thanks were expressed to these lecturers and also "to J Millington, Esq, late Professor of Natural Philosophy in the Royal Institution of London who is engaged on a most able series of lectures on astronomy". The society at that time was investigating the principles of water wheels, inquiring into the causes of the numerous explosion of boilers in American steam boats, and the *Journal* for 1833 and 1834 contains reports of various individuals into the system of weights and measures of the United States, England and France Its important work in this direction was recognised by the Pennsylvanian Government, and on the instructions of the House of Representatives the secretary of the Commonwealth had forwarded to the Institute a draft of a bill relating to weights and measures for its consideration

Societies and Academies

LONDON

Royal Society, January 25 A. ZOOND and J EYRE. Studies in reptilian colour response. (1) The bionomics and physiology of the pigmentary activity of the chameleon In strong diffuse daylight chameleons become dark on a black background and pale on a white one Blind animals darken in the light. This response depends upon the integrity of spinal reflex arcs The time relations of these responses have been determined. The threshold for the retinal photoreceptors is lower than for the dermal ones In weak light the white background response is reversed, the animals becoming dark Low temperatures above 0° C have no effect upon the normal response of chameleons to darkness A theory of nervous coordination is developed It is suggested that the 'daily rhythm' of colour changes may be interpreted in terms of the white background response in strong and weak light, without reference to temperature. A WOLSKY and J S HUXLEY The structure and development of normal and mutant eyes in *Gammarus chevreuxi* The eyes of 'eye colour mutants' ('red', 'no-white', etc) differ from normals only in pigmentation and not in structure The eyes of 'eye-structure' mutants ('albino', 'colourless') are markedly deficient as compared with normal For the development of normal eyes, the results of Schatz (1929) are confirmed The differentiation and growth of the optic tract (not previously studied in *Gammarus*) is centrifugal in time the medulla externa and lamina ganglionaris are at first small, but eventually constitute a large and distinct protuberance In the eye-structure mutants the adult optic tract is comparable with the early embryonic stage of normals The structure of albino and colourless eyes can be formally explained in terms of (*a*) a rate-gene causing a delay in differentiation of the organs (optic tract and eye-mass) derived from the primary optic disc, (*b*) a graded distribution of the inhibitory effect caused by this delay, and (*c*) possibly, the consequent absence of a formative stimulus normally exerted by the optic tract upon the differentiation of the eye proper. J. NEEDHAM, C H WADDINGTON, and DOROTHY M. NEEDHAM Physico-chemical experiments on the amphibian organiser The induction of a secondary embryonic axis in amphibian gastrulæ can be accomplished by the implantation of (*a*) cell-free extracts of the neurula, (*b*) ether and petrol-ether extracts of the neurula, (*c*) adult amphibian tissues, (*d*) ether extracts of adult amphibian viscera A distinction is made between two factors in induction, the production of an embryonic axis as such, which is called evocation; and the determination of the regional, for example, antero posterior, character of that axis, which is called individuation The evocator is probably a definite chemical substance soluble in ether and petrol-ether.

PARIS

Academy of Sciences, December 18 (*C.R*, 197, 1545–1705) LOUIS CARTAN The displacement in an electrostatic field of magneto-electronic spirals. N. THON: The direct determination of the number of active centres on a crystalline metallic cathode. E GUILLERMET: The electrolysis of cupric chloride in methyl alcohol solution. The primary reaction appears to be production of cuprous chloride and chlorine. R DE MALLEMANN and H. COURTILLOT. Elliptical reflection at normal incidence on a transparent anisotropic body. The superficial double refraction of Iceland spar. ANTOINE GOLDET: The thermal variation of the magnetic double refraction of nitrobenzene, benzene and carbon disulphide. The experimental results are given as curves, and are compared with those predicted by the theories of Langevin and of R. de Mallemann. TSAÏ BELLING. The magnetic double refraction of gaseous oxygen. Experiments carried out with a field of 45,000 gauss show that compressed oxygen under the action of the magnetic field clearly acquires a negative double refraction proportional to the pressure. J J TRILLAT · Study of the fatty esters of cellulose by means of the X-rays The reticular distances are a linear function of the number of carbon atoms in the esterifying acid HUBERT GARRIGUE · The activity of materials exposed to the natural electric field G GAMOW and S. ROSENBLUM: The effective diameters of the radioactive nuclei F JOLIOT An experimental proof of the annihilation of positive electrons The experiments show that when positive electrons are absorbed by matter, there is observed an emission of photons of energy about 0·5 × 10^6 ev. Hence it is concluded that the process of annihilation of positive electrons imagined by Dirac is confirmed by these experiments FRANCIS PERRIN · The possibility of the emission of neutral particles of intrinsic mass zero in β radioactivity W M. Co-ordination of State Scientific Services

IN his recent presidential address to the Royal Society, Sir Frederick Gowland Hopkins referred at some length to the Medical Research Council and its relations to the Agricultural Research Council and the Advisory Council of the Department of Scientific and Industrial Research Stressing the relations which have from their inception existed between the three councils and the Royal Society, Sir Frederick suggested that their creation and the definition of their respective duties and relations had brought into being a great national research organisation, to be viewed as a whole and fully worthy of the confidence of the Society and of Great Britain Although even to-day it is not fully understood by statesmen that endowment of research is among the most profitable of national investments, scientific men are now in real control of scientific policy in Britain even when it deals with enterprises endowed by the State

This reference to the relations which exist between various research councils and research associations deriving part, at least, of their endowment from the State, is welcome in view of certain charges which have recently been brought against them, arising out of the conduct of investigations which are of general interest not only to industry or to social institutions but also to the defence forces of the realm. Two of the most characteristic features of modern scientific development are, indeed, on one hand the extent to which co-operation between different classes of scientific workers—medical men, physicists, biologists, chemists, engineers and others—is again and again required for the solution of a scientific or industrial problem, and on the other, the extent to which discoveries or advances in one field or industry find direct and ready application in many other quite unrelated sciences or industries.

It is accordingly obvious that the Privy Council, under the ægis of which the work of the Medical Research Council, the Agricultural Research Council and the Department of Scientific and Industrial Research is conducted and secured from the dangers of political vagaries and the inhibitions of departmental interference, should take measures to avoid overlapping of effort and the duplication of any expenditure of national revenue. Careful provision has been made to secure adequate contacts within the triad of councils A nexus of responsibilities has been established The three secretaries, for example, are under obligation to meet together on specific occasions for a general discussion of policy, one member at least of the Medical Council must always be on the Agricultural Council, and there are other means of securing co-operation In spite of the diversity of researches and enterprises associated with each of these councils, effective co-ordination has been possible to a remarkable extent The dissolution by the Committee of the Privy Council in 1929 of the three co-ordinating research boards for chemistry, physics and engineering, which were originally established in 1920, is in itself evidence of the success with which research is being co-ordinated

The realisation of the many-sided interests and applications of particular pieces of scientific research undoubtedly led to the adoption of the policy of appointing special *ad hoc* committees from time to time for the consideration of practical problems Such committees are sometimes departmental committees, but the particular department which initiates or bears the responsibility for their work may afford little or no indication of the extent of the interest or application of that work, which might in fact have been equally initiated by several other departments or research organisations

The specific charge has recently been made in "Patriotism Ltd", a publication of the Union of Democratic Control, that the Department of Scientific and Industrial Research has expended a large sum of money on fundamental war research work and on the reorganisation of the research work of the fighting services, and also that the Medical Research Council is similarly financing scientific preparations for war A careful scrutiny of the published reports shows that in actual fact the whole of the expenditure of the Department of Scientific and Industrial Research has been in research work the results of which have been and are available for industry It is similarly true that the Medical Research Council has not since the War period undertaken or financed any researches for purely warlike purposes such as, for example, investigation of the effects of chemical warfare

In view of what has already been said about the general interest of the results of many scientific investigations, it would be highly unlikely that the results of some of the investigations undertaken from purely industrial or medical motives would not have a great interest for some of the fighting services. Equally, in view of the care which any sound administration must take to secure that neither Civil votes nor the Defence votes are used to pay for the same work to be done twice over, it would be surprising to find that no work had been undertaken by the Department of Scientific and Industrial Research or the Medical Research Council at the request of one of the defence services

As a matter of fact, the evidence even of the examples cited in justification of its charges by the publication to which we refer indicates that the converse may equally be true Reference is made, for example, to problems of visual research, on which the Medical Research Council have published a report on "Colour Vision Requirements in the Royal Navy" The results of these investigations, though of special application to service conditions, have also great interest for the merchant marine, the railways, and in relation to road traffic and to some industrial operations

This matter of visual research illustrates a further possibility which criticism has to weigh The Medical Research Council has on occasion availed itself of favourable opportunities afforded by conditions in the defence services for the investigation of problems of interest to the Council This applies particularly in regard to investigations on the value of psychological tests for the selection of personnel for particular forms of skilled work Such investigations are, of course, initiated directly for the assistance of industry The investigations on special aptitudes required in rifle shooting were not undertaken at the instance of the military authorities but of the academic psychologist who did the work, and who saw in rifle shooting an operation combining manual, visual and psychological factors which was particularly suited to his study, and naturally found soldiers the most convenient source of material

Equally it is unfair to charge the Medical Research Council with financing war research when it borrowed special apparatus and trained personnel from the Chemical Defence Research Department for the investigation of the dust clouds that are associated with particular industrial processes and that are likely to be injurious to the workers Similarly, the Council has drawn on the special knowledge of acoustical problems acquired by the Services in relation to anti-aircraft defence to assist its work on the physiology of hearing, which is primarily aimed at the alleviation of deafness.

It is impossible to assess fairly the work of the

Medical Research Council in such matters if constant regard is not paid to the obvious fact that there are few branches of medical research in which new knowledge will not advance military as well as civilian science "Patriotism Ltd" also refers to investigations carried out under the Industrial Health Research Board on the value of psychological tests for accident proneness, in which tests were made on a group of air pilots, naval artificers and dockyard apprentices as well as omnibus drivers The results of some of these tests have already been published in a report by E Farmer, E G Chambers and F J Kirk, on "Tests for Accident Proneness", and they have already been utilised by the National Institute of Industrial Psychology as a basis for a series of practical tests which can be utilised alike for the selection of the best drivers from among a number of applicants, selection of the men most suitable for training as motor drivers, for discovering what is lacking in drivers of poor ability in order to remedy their deficiencies if possible, or for advising those who intend to learn to drive what degree of ability they are likely to develop The value of such practical tests as a means of reducing road accidents is obvious, and the studies upon which they are based are a direct contribution to the welfare of the community, which justifies the use of any available material for its acquisition

The criticism which has been levelled at the Medical Research Council and the Department of Scientific and Industrial Research arises fundamentally from that failure to grasp the passing of the essential distinction between combatant and non-combatant which holds up progress in disarmament If the fundamental lesson of the War years 1914–1918, that under modern conditions war has become industrialised and now involves whole populations and not merely armies, navies or air forces, were widely appreciated, disarmament itself would receive a firmer backing and such criticism as that we have been discussing would never be advanced

There is, however, one point of significance on which the chapter in "Patriotism Ltd" does well to focus attention It would be indefensible if results of civil research held available for use by industry were not also made available for the defence services It would be equally indefensible if work undertaken at the instigation of the fighting services, but not specially paid for by contributions from their vote, were not published and made available for use in industry.

There does not appear to be any reason to suppose that publication encounters any opposition, so far as the researches undertaken under any of the co-ordinating *ad hoc* committees and the like are concerned The Department of Scientific and Industrial Research, however, has initiated a number of co-operative research associations which are financed partly by the Department and partly by the industries concerned These associations, being on a voluntary basis, are by no means completely representative of the industries they serve, and a good deal of jealousy is encountered from time to time on the part of firms which are members of such associations as to the results of their investigations being available for non-members Direct opposition of industrial firms to a policy of publication can in fact place the Department in a delicate situation, and since the work of a number of the associations has a direct bearing on problems confronting the defence forces, it can easily happen that industry itself may be responsible for withholding complete publication of the results of such investigations

Under modern conditions, therefore, it is essential that the research activities which are partly or wholly endowed by the State should be planned and co-ordinated in relation to the needs of the State as an organic whole and not on sectional lines Any attempt to discriminate too rigidly between the needs of a particular department of State and industry is likely to involve us in acute difficulties if duplication of effort is not to result This is, of course, not to deny the essential principle that, for example, such departments of State as the Medical Research Council or the Department of Scientific and Industrial Research, should not directly support researches which are primarily of interest to the fighting services and the expense of which should be borne by their own vote

Sir Frederick Gowland Hopkins has pointed out that scientific men are now in real control of scientific policy in Great Britain, even when it deals with enterprises endowed by the State Accordingly, much undoubtedly does depend upon the sincerity and loyalty with which scientific workers discharge their trust Except with their connivance and responsibility, funds allocated for civil purposes cannot be used for the endowment of researches for the benefit of the fighting services which should properly be a charge on votes for the latter purpose On their integrity the community must rely for ensuring that the civil vote is used entirely for civil purposes, whether or not defence purposes are served at the same time

It has to be remembered that scientific workers in Government service can only enter a protest against policy by leaving the service A State department could not tolerate criticism or opposition from its own servants, and the responsibility for determining what constitutes honourable conduct in regard to specific duties lies with the profession as a whole Accordingly, a healthy position and loyalty to the highest ideals are ensured as much by a widespread public spirit on the part of scientific workers generally as by the conscientiousness of individual workers The existence of such a public spirit would not only afford full professional support to those members in actual Government service in the unlikely event of need, but also would induce scientific workers to take an active part in educating public opinion as to the true functions of research in the modern State

Obtrusive Legislation

THOSE who have reason to know that infertility has an economic value, and that deliberate family limitation has been a factor of some importance contributing to their own social elevation, and wish to share with others the information and the practices which have been helpful to themselves, who hold the view that sex is not to be justified solely because of its relation to reproduction, and who think that parentage should be deliberate and voluntary and not casual and accidental, must necessarily wish to examine with the utmost care any proposed legislative measure which deals with the subject of contraception

At the present time, a Bill, presented by the Lord Dawson of Penn, and entitled "An Act to Restrict the Sale, Display and Advertisement of Contraceptives", is before the House of Lords and comes up for its second reading almost immediately A superficial examination of this Bill would yield the conclusion that no serious objection could be taken to its terms Its purpose is to make it illegal (1) to sell or offer for sale in any street or public place, or by means of an automatic machine so placed that it can be used by persons in any street or public place, any contraceptive, (2) to go to the premises of any person and there sell or offer for sale any contraceptive, unless the sale or offer is made in pursuance of a previous request of that person, or the premises are used by a dealer in contraceptives who buys to sell again, (3) to display in or outside any shop so as to be visible to persons outside the shop any contraceptive, or any picture or written description of any contraceptive; (4) to send or deliver, or cause to be sent or delivered, to any unmarried person who has not attained the age of eighteen years any circular or other document containing information of any kind whatsoever relating to any contraceptive

From the fact that the Bill is sponsored by Lord Dawson, who has long been an advocate of birth control, and several years ago, at the Church Congress at Birmingham, stated publicly that he was in favour of contraception, it may be assumed that the Bill is intended only to shield inexperienced youth from the stimulus of the pornographic, it certainly would make it impossible for such to indulge in sexual intimacy completely freed from its more grievous repercussions To rid the streets of touts and hawkers, and to force a certain kind of shop to adopt a different form of window-dressing is a truly commendable ambition, and if the sole effect of the Bill could be that those people who should use contraceptives would, in the future, obtain them easily from reliable and responsible sources, no one could cavil at it No one would, if it were the case that birth control clinics were an integral part of the municipal and State medical services, as they might be. But, can one be sure that the difficulties this Bill creates in the matter of obtaining contraceptives will really affect the incidence of promiscuity? May it not be that its main effect will be an increase in illegitimacy and in venereal disease?

The obtrusive display of contraceptives may be objectionable, but from the point of view of the State it is nothing like so wicked as bringing unwanted children into the world It may be assumed that in the immediate future, at any rate, the Bill, becoming law, would certainly tend to reduce the purchase of, and therefore the use of, contraceptives, not only by unmarried youths but also by those who, in the interests of themselves and of society, should use them for the limitation of their own families. The very ugliness and the vulgarity of the shop window can possess an educational value, revealing to the ignorant necessitous the fact that contraceptives exist In the opinion of many, this Bill, in the light of modern scientific thought upon the subject of birth control, must appear to be somewhat reactionary and deplorable; it interferes with the liberty of the individual, it hits others besides those at whom it is aimed, and it must interfere with the democratisation of contraception—one of the most socially valuable of all biological inventions. The further history of this Bill will show whether or not there is in the present Parliament anyone who can claim the privilege of wearing the mantle of Bradlaugh

---

Position of British Broadcasting

The B.B.C. Year-Book, 1934. Pp 480 (London: British Broadcasting Company, 1934.) 2*s*

THERE is much of interest in this year-book We learn that for every fee of 10*s*. paid by a listener for his licence the Government takes 5*s* 5*d* and the B B C gets 4*s* 7*d* By issuing publications helping broadcasting, the B B C manages to increase this sum to 5*s* 10*d* per licence. A considerable amount of the energy of the management, therefore, must be spent in helping forward their publishing business It seems a pity that the B B C. has no capital resources and that all capital expenditure must be provided out of income Considering its national importance, it is not good policy that it should be cramped in this way

It would be interesting to know the reason why Hertfordshire is the county of England which has the greatest number (20) of licences for every 100 inhabitants. It is easier to see why Oxfordshire, Cambridgeshire and Surrey come second with 17. On p. 89 we are told that some 4,000 schools take broadcasting lessons, 80 per cent being elementary Obsolescence of sets, reorganisation and transfer of teachers are given as causes why some of these lessons have been discontinued. There can be little doubt that the difficulty experienced in obtaining a trustworthy standard set for reception has greatly hindered progress. We are glad that the Council of the B.B C and the Department of Scientific and Industrial Research have prepared a list of sets on the market suitable for school use. Negotiations are also being made with the Radio Manufacturers' Association regarding the development of a hire service and maintenance system. We are sure that if these facilities were available more schools would employ the new medium.

Parts of the technical section of the year-book are of special interest to the electrician. There is an excellent chapter on the calculation and measurement of field strength. Not only are the best practical formulæ given but their limitations are also pointed out. The usual formulæ postulate that the electrical conductivity of the earth is homogeneous throughout its mass. They also neglect the existence of hills and buildings. The proper corrections to be applied to the formulæ can only be learnt by experience. The would-be calculator need not, therefore, be disappointed if the measured values differ very appreciably from those calculated

We were disappointed to find that little reference is made to the scientific and engineering research work being carried out by the B B C The science of broadcasting is an outcome of applied physics, and judging by the rapid progress made in similar applications where research laboratories are considered necessities, scientific workers would like assurance on this point. The B B C must know, as well as the manufacturer, the more urgent problems that have to be solved, and it has many facilities for experimenting which are not available to the industry Continuous scientific and mathematical research is necessary if the B B C stations are always to be in the front rank In the next edition we should like to see the names of the engineers and scientific investigators employed by the B B C. and an account of the researches they have made and the progress achieved during the year

The Institution of Electrical Engineers has formed a committee to combat electrical interference with broadcast reception. It is composed of representatives of all the many interests concerned, including the B B C and the Post Office engineers. Various subcommittees have been formed to examine the problem and see how it can be remedied The disturbances that arise due to various classes of interference-causing apparatus are specially considered

We were glad to read about the short-wave work carried out last year both on the transmitting and on the receiving side. Particular attention was paid to the relative effectiveness of the many forms of aerial which are available at present The closing down of 5 XX and 5 GB when the new Droitwich station is completed will provide accommodation and space suitable for research work. Experimental work has been carried out at the receiving post at Tatsfield in Surrey. A new receiver suitable for relaying programmes from distant short-wave stations has been developed.

Problems on acoustics were continuously studied during the past year. Every new building that has to be adapted for studio purposes gives rise to new problems which can only be solved by research One of the problems is how best to insulate a studio from the sound waves coming from the other studios and from street and other noises

We are glad to read that the B B C is affording help to further the progress of the art of television For some years past experimental work has been going on with 30-line television transmitted by the ordinary transmitters used by the B B C A new line of research—television of the high definition type—is now being undertaken This type cannot be transmitted on the ordinary wave-lengths owing to the width of the side-band which is necessary These experiments are being conducted on ultra-short wave-lengths by means of a special transmitter erected on the roof of Broadcasting House This transmitter is capable of transmitting side-bands of 500 kc /s (about 600 metres) on either side of the carrier wave No 16 Portland Place has now been prepared as a large television studio, with a suitable sound accompaniment A stage is provided for the actors and an auditorium for the visitors Everything is ready for television programmes to be transmitted from this studio

The breakdown record for all the B B C stations is quite satisfactory The breakdown time consists largely of the time necessary to replace valves in those cases where it is not possible to switch in a spare valve without closing down The whole breakdown time in 1933 is equivalent to an average of 57 minutes per annum per transmitter

British Dyes

The Synthetic Dyestuffs and the Intermediate Products from which they are Derived Being the seventh edition of "Cain and Thorpe" entirely rewritten and enlarged By Prof Jocelyn Field Thorpe and Dr Reginald Patrick Linstead Pp xv + 472 (London Charles Griffin and Co , Ltd , 1933) 30*s* net

DYESTUFFS are of interest from two aspects, that of science and that of economics—we had almost written politics The story of the attempts, now happily attended with complete success, to create a British dyestuffs industry during and subsequent to the War is an oft told one Whereas 90 per cent of the colours used in Great Britain came from Germany in 1913, it is possible to write twenty years later, in 1933, that 90 per cent of the production required for the home market is made in Great Britain

An Act of Parliament was passed in 1920 prohibiting the importation of dyes and intermediates, except under licence, for a period of ten years, and a machinery, in the form of a committee, was established for granting licences which comprised representatives of both users and makers, the former being in the majority In addition, a representative committee was set up under the Board of Trade to advise in regard to the development of the industry This machinery has worked well, largely owing to the goodwill shown by all parties

Since the expiry of the period contemplated in the Act, this has been renewed from year to year under the Expiring Laws Continuation Act, until in 1933 the whole question of dyes was referred to the new Import Duties Advisory Committee, which took evidence from all the interests concerned Its considered report advised the Government that protection of dyes on the existing lines should become part of the permanent legislation of Great Britain and a bill giving effect to this intention has recently been passed by Parliament The dyestuff legislation has been strongly opposed on political grounds ever since its inception this has had an adverse effect on the recovery of the industry, which in consequence has been faced at times with considerable uncertainty as to the future It is hoped that the final settlement of the matter will remove dyes once and for all from the arena of politics, and so give the industry full scope to develop as the result of its intensive research programme

The book before us, which prompted these comments, was first launched by Cain and Thorpe in 1905, the former having had practical experience in industry During the arduous days when we were trying to build up the industry in Great Britain and train chemists from other spheres in the intricacies of dyes, it played a part of definite utility, as witnessed by the rate at which the various editions were exhausted

The last few years have seen many changes in the relative importance of the various groups of dyes, so that it has become necessary entirely to rewrite the subject for this, the seventh, edition, giving much more prominence to certain branches It is some years since Dr Cain passed away, Prof Thorpe has now the assistance of a younger colleague, Dr Linstead, who has already made a name as a research worker in this field

The book follows familiar lines; naturally it is largely structural formulæ, without which this branch of chemistry could not be intelligible—more than a word of praise is due to all concerned for the clear manner in which these are produced The three sections into which it is divided comprise the intermediates, the dyestuffs and a practical one giving precise directions for the preparation of a considerable number of substances

Criticism in detail of such a compendium is of interest only to the expert, it will be of more value perhaps to indicate the lines along which most progress is being made Outstanding is the general movement towards the production of faster dyestuffs, particularly the vat dyes of the anthraquinone series This has in part been made practicable by the greater availability of anthraquinone itself, prepared from naphthalene by the very striking modern aero-oxidation method The story would be incomplete also without mention of the discovery of 'caledon jade green', the best green vat dyestuff The second line of development has been the production of dyestuffs suitable for viscose and acetate silks, which has been attended with a success obvious to all of us Mention may be made of the 'ingrain' colours produced from the coupling components direct on the fibre, of the self-mordanting 'neolan colours' and of the 'indigosol' solubilised leuco esters

The main facts of the dyestuffs story have been driven home to the nation—research and always more research, research which makes us prepared for war and strong in peace, always finding new wonders of applied organic chemistry Nature is full of colours, as James Joyce writes, "they glow and fade, hue after hue, sunrise gold, the russet and green of apple orchards, azure of waves". yet man has been able to surpass them in brilliancy if not in beauty with his synthetic dyes

The work will take its place on our shelves as the standard textbook on its subject E F A

Structure and Development of Man

Human Embryology and Morphology. By Sir Arthur Keith. Fifth edition Pp viii + 558 (London Edward Arnold and Co, 1933) 32*s*. 6*d*. net.

THIS, the fifth edition of Sir Arthur Keith's textbook, will be heartily welcomed, as it has occupied for many years a somewhat unique position It embodies various distinct improvements over the fourth edition which appeared in 1923, but in spite of the accumulation of new facts and new points of view since that date, the author is to be congratulated on having been able to preserve the volume from undue expansion His clear and popular style of exposition conveys to the readers whom he has in view—students of medicine—the end results of the work of embryologists better than perhaps any other textbook The text is reduced to the minimum consistent with clarity Much detail has necessarily been omitted, but the needs of the medical student have been in this respect kept in view Although ideas differ regarding the relative importance of facts of observation and interpretation, Sir Arthur Keith's selection, in view of his long and varied experience, may be accepted, at least so far as organogenesis is concerned, as satisfactory

The old title of 1901 is perhaps rather out of date Descriptive embryology has now become largely merged in a new and more comprehensive morphology, and in this connexion the author's introduction of a new chapter on "Experimental Embryology" is to be commended The text of the old description has not been greatly altered, but it is fully brought up to date, and the addition to each chapter of a bibliographical appendix—coupled with notes—constitutes a valuable improvement The notes provide material for a different class of reader from the elementary text Many deal with more abstruse and doubtful points, and open vistas regarding the most recent advances, while the references to literature send the inquiring student to the sources where he will find—what the keener senior student desires—some knowledge of the actual evidence in sections and reconstructions from which the story has been compiled, and upon which the purely diagrammatic illustrations are founded These last have not been greatly added to, but we welcome some newcomers which show the same ingenious and informing quality as the old

The chapters on organogeny maintain the old level of clear elementary description which has given this textbook the success it has attained The section on the early stages of development is perhaps scarcely so successful It is relatively more popular and introductory This is inevitable without the use of more comparative data critically considered, but as a brief introduction it may serve sufficiently well the aim of the book as a whole. T. H. B

Short Reviews

Thermodynamics Applied to Heat Engines: a Textbook covering the Syllabuses of the B.Sc. (Eng.) and A.M.I.Mech.E. Examinations in this Subject. By E. H. Lewitt. (Engineering Degree Series.) Pp. x+347. (London: Sir Isaac Pitman and Sons, Ltd., 1933.) 12s. 6d. net.

A very useful account is given in this book, from an engineering point of view, of the application of thermodynamics to the theory of the steam engine, mechanical refrigeration, steam nozzles, steam turbines, fuels and the internal combustion engine. Students reading for the final examination for an engineering degree should find the accounts of these applications helpful. The author states that the "subject has been methodically developed from the fundamental laws of experimental physics". His attitude towards some of these fundamentals may be gauged from the quotations following, which the reviewer gives without comment.

"It has been calculated that a gas will occupy no volume at a certain low temperature known as absolute zero temperature . . . The accuracy of the assumption . . . is extremely doubtful, as the gas would liquefy . . . before this low temperature is reached."

"A perfect gas is the name given to the natural state of any substance of which the evaporation from the liquid state is complete."

"Liquids and solids have one specific heat only; but a gas is regarded as having two distinct specific heats . . ."

"Boyle found experimentally that when a gas is heated at a constant temperature the pressure multiplied by the volume remains constant."

"Entropy cannot be regarded as a physical property of the fluid; it is an imaginary property which was devised by Rankine and is used by engineers as a means of providing a quick solution for problems dealing with the adiabatic expansion of vapours." A. F.

Experimental Electrical Engineering and Manual for Electrical Testing for Engineers and for Students in Engineering Laboratories. Vol. 1. By Prof. V. Karapetoff. Revised by Prof. Boyd C. Dennison. Fourth edition, completely revised and reset. Pp. xxviii+781. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1933.) 37s. 6d. net.

This volume is written for engineers and for students in engineering laboratories. It contains very few mathematical formulæ and very little theory. It will be useful to electricians in testing laboratories and to students who have a wide elementary theoretical knowledge of the subject. As a work of reference it will be of value; the methods of testing given are good and many of them are standard methods in the United States. The methods given of diagnosing the causes of faulty running in machinery can also be recommended. We notice that in this edition the chapters on telephone practice have been omitted and also the chapter on primary cells. The book therefore deals more exclusively with heavy engineering.

Direct and Alternating Currents: Theory and Machinery. By Prof. E. A. Loew. Pp. xiii+656. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1933.) 27s. net.

In this volume the author reviews the theory of the electric circuit and the operating principles of electric machinery. The applications of electricity are now so numerous that it is very difficult to decide what to describe and what to omit. That everything has to be included in one volume makes it necessary to pass lightly over much theory, and since the student will in his future practice come across many types of equipment some of which it is necessary to describe, there is practically no space for modern theory. Luckily the laws and principles necessary to understand the performance of everyday electrical machines are few in number. The author has made a happy selection and the book will be useful to the technical student.

Practical Acoustics for the Constructor. By C. W. Glover. Pp. xi+468+27 plates. (London: Chapman and Hall, Ltd., 1933.) 25s. net.

There is little excuse nowadays for a badly designed hall, church or theatre—badly designed, that is to say, from an acoustic point of view. The principles which govern acoustic design are very well understood, and the number of books dealing with architectural acoustics is legion. Mr. Glover's addition to the list may be recommended as a thoroughly practical volume, designed for the use of practising architects. The information given is very full and detailed, and the work forms a most useful book of reference. There is a remarkable bibliography appended to the volume. A. F.

The Great God Waste. By John Hodgson. Pp. viii+127. (Eggington, Beds.: John Hodgson, 1933.) n.p.

Arguments are more likely to prove weighty in the absence of exaggerated presentment, and may easily show fallacies in depending upon statistics. Issue may be joined with the remark, that taxation impoverishes one class to enrich another; and the glorification of leisure as the *dolce far non troppo*, in place of an honest day's work, as hitherto understood, is to be deplored. Mr. Hodgson has wandered up and down and to and fro, with the amazing resultant discovery, that the U.S.S.R. deserves praise at the expense of the rest of the world. The trend of events during the last few months serves to discount the value of much of Mr. Hodgson's text. P. L. M.

Heavy Hydrogen and Heavy Water

IN a lecture delivered before the New York Section of the American Chemical Society on December 8, Prof. H. C. Urey gave some further information as to the properties of the heavy hydrogen isotope of mass 2·01356, that of light hydrogen being 1·00778 (both on the $O^{16} = 16$ scale).

Attempts had been made to separate the hydrogen by fractional distillation of the liquid, calculation showing that the vapour pressures should be different, but the method was not successful because the low surface tension of liquid hydrogen makes it difficult to prevent its escape as mist in the fractionating column. A method depending on diffusion into flowing mercury vapour was no more effective. Some details of the actual method of separation, depending on electrolysis with water-cooled nickel electrodes in cells each containing 300 c.c. of potash solution in water from commercial cells enriched to 0·5–1 per cent of "deuterium oxide", are given. The current is 25 amp., and 30 cells are placed in series across 110 volts. Electrolysis is carried on until the volume is reduced to one third, when the residual electrolyte is removed, two thirds distilled from the potash, and combined with the undistilled liquid. Electrolysis to one third is again carried out, and beginning with the second stage, the hydrogen and oxygen gases are recombined to give a liquid containing 0·3–0·4 per cent of "deuterium oxide". The progress of the fractionation is followed by observation of the refractive index.

Investigations on the equilibrium

$$2H^2I \rightleftharpoons H^2_2 + I_2$$

gave results agreeing with calculations which show, for example, that the ratio of the equilibrium constants with light and heavy hydrogen should be 1·222 at 700° abs. The equilibrium constants for the reaction

$$H^1_2 + H^2_2 \rightleftharpoons 2H^1H^2$$

gave 3·28 (3·27), 3·73 (3·77) and 3·75 (3·82) at 298·1°, 671° and 741°, abs., the calculated values being in brackets[1]. Experiments by Crist and Dalin showed that no interaction between heavy hydrogen and the light hydrogen of water over which the gas was confined had occurred in a few weeks; the different result reported by Oliphant[2] may have been due to the presence of a catalyst.

Experiments by Rittenberg and Urey on the electrolytic separation of hydrogen isotopes pointed to a kinetic explanation of the phenomenon; unless the differences in electrode potentials are much greater than those indicated by calculations, it does not seem possible that the separation is due to this cause[3]. The physiological properties of heavy water are supposed to depend on possible differences in ionisation constant and in reaction velocities as compared with ordinary water.

A design of electrolytic cell for concentrating heavy water has been described by Harkins and Doede[4] but no details of performance are given. The specific rates of discharge of light and heavy hydrogen atoms on various metal cathodes have been measured by Topley and Eyring[5] and the results considered with reference to the theory of over-voltage: they are not inconsistent with the view that the separation is almost entirely due to the zero-point energy difference. The slow process at the cathode does not appear to be combination of atoms to molecules.

A method for determining the concentration of the heavy oxygen isotope O^{18} in water during treatment[6] depends on decomposing the heavy water with heated iron and combining the liberated hydrogen with ordinary oxygen from hot copper oxide and condensing the water (X) so formed. The iron oxide is then decomposed by heating in ordinary hydrogen and the water formed (Y) condensed. The water X was found to be identical with the initial heavy water, whereas Y was identical with ordinary water. Hence there is no appreciable concentration of O^{18} in the electrolytic process.

Several investigations of the properties of heavy water, in addition to those already reported in these columns[7], have been published. The solubilities of one or two salts in heavy water are distinctly lower than in ordinary distilled water[8]: 1 000 gm. of ordinary water dissolves 0·359 gm. of sodium chloride at 25° and 1 gm. of water containing 92 per cent of hydrogen as H^2 dissolves 0·305 gm., a difference of 15 per cent, whilst the corresponding figures for barium chloride show a difference of 19 per cent.

The densities, refractive indices (n^d_{20} and n^c_{20}), molar refraction for D line, viscosity (η), surface tension (γ), dielectric constant (D), magnetic susceptibility (χ) and molar susceptibility of water containing 31, 63·5 and 92 per cent hydrogen as H^2 (assuming the density 1·1056 for pure H^2_2O) have been measured, and the values extrapolated to pure H^2_2O. Selwood and Frost's values[9] are (the values for ordinary water in brackets): n^d_{20}, 1·3281 (1·3329); n^c_{20}, 1·3265 (1·3309); η_{20}, 14·2 mp (10·87 mp); γ, 67·8 (72·75); $\chi \times 10^6$/gm. (92 per cent water), $-$0·65 ($-$0·72); molar susceptibility $\times 10^6$, $-$13 ($-$13).

Lewis and Macdonald found the viscosity at several temperatures (5°–35°) higher than that of ordinary water, but their value at 20°, 12·60, is not in agreement with Selwood and Frost's. The dielectric constant is lower than that of ordinary water: $D^2/D^1 = 0·982$ at 10°, 0·990 at 25°. The abnormality as compared with ordinary water decreases with rise in temperature for all properties investigated.

The refractive index[10] affords a convenient method of determining the proportions of H^2_2O

and $H^1_2O^{18}$ the effect of the O^{18} isotope is opposite in sign from that of H^2, and the measurement of the density and refractivity gives the complete isotopic composition (H^1, H^2, O^{16}, O^{18}) of a sample of water The mutarotation of *α-d*-glucose in heavy water shows that the displaceable hydrogen atom of the sugar is immediately replaced by H^2 from the water, and the mutarotation is due to a change in which the double bond in a carbonyl group, – C=O, is replaced by a ring formed by the migration of a hydrogen atom[11]

By the interaction of heavy water with magnesium nitride, ammonias in which the hydrogen atoms are predominatingly H^2 (deutero-ammonias) are produced, which have higher melting points, boiling points and latent heats than ordinary ammonia[12]

Further experiments on the physiological effects of heavy water[13] show that the filaments of *Spirogyra* in water of specific gravity 1 000061 are characterised by lack of movement, absence of abscission or cell disjunction, and greater longevity The usual effect with ice and steam water was confirmed[14] The results suggest a stabilising action of water containing H^2, perhaps an effect on the colloids in the organism, the water bound in such colloids being known to be denser than free water A slightly higher *p*H (as determined with bromthymol blue) for this sample of water was found. In other experiments[15], decreased enzyme activity and fermentation in isotope water, a more extensive spread of *Oscillatoria* (perhaps due to a *p*H of 6 77 as determined by the glass electrode), and the following results with *Spirogyra nitida* were found · a representative filament of 31 cells in isotope water had 43 cells after 6 days, of which 3 were dead , a filament of 37 cells in ordinary water showed no cell division at the end of 6 days and 20 cells died , in ice water renewed twice daily, a filament of 50 cells showed 15 abnormal at the end of five days, whilst the filament in freshly condensed water renewed twice daily showed all its 50 cells dead or shrunken in the same period , the control filament (pond water) had 47 cells initially and 64 normal cells after six days

Ernst Haeckel (1834-1914)

By PROF. E W MACBRIDE, F R S

THE career of Prof Ernst Heinrich Haeckel, the centenary of whose birth falls on February 16, belongs to the heroic stage of the history of the theory of evolution In 1862, at the early age of twenty-eight, he was appointed to the chair of zoology in the University of Jena, a post which he held until his death in 1914

Haeckel's life bears a strong resemblance to that of Huxley, for like Huxley his life's task was propaganda in favour of the theory of evolution against the then prevalent theory of the origin of species by a series of supernatural interpositions of the Divine Being Like Huxley too, he was an ardent advocate of the animal origin of the human race But there were marked differences between the two men , Haeckel was a harder hitter than Huxley, and withal a much more reckless one, since he was apt to make wild statements on the basis of insufficient data, as, for example, when he stated that if there were a line to be drawn between animals and men, the lower races must be included amongst the apes The most recent anthropological studies seem to indicate that in the essential make-up of their minds the most primitive men are very like ourselves · the data and presuppositions from which they start are different and so are their customs and traditions, but granted these postulates the conclusions at which they arrive are natural enough But on the whole, Haeckel was a sounder biologist than Huxley whilst he embraced with enthusiasm Darwin's arguments about natural selection, he was never deceived into thinking that the mere survival of some and the death of others could account for progressive evolution he saw quite clearly that the vital question was the origin of the 'variations' which distinguished the survivor from his less fortunate brother, and in this matter he followed Lamarck When he popularised his views in his famous "History of Creation" he dedicated the work to "Jean Lamarck and Charles Darwin"

Haeckel excelled Huxley also in the amount of actual zoological work which he accomplished Thus he wrote a descriptive monograph of the Radiolaria collected by H M S *Challenger*, giving the characters of no less than 3,600 new species This work occupied him for ten years He also monographed the calcareous sponges, but the greatest task which he attempted was to sketch, assuming the truth of the evolution theory, the actual course which evolution had pursued in producing modern plants and animals His conclusions were embodied in his "Allgemeine Morphologie", of which the "History of Creation" may be regarded as a popular edition Of course, the state of zoological and botanical knowledge at the time that these books were written was far too incomplete to permit of any but the vaguest sketches of the course of evolution, but there can be nothing but admiration for Haeckel's bold adventure. In the circumstances, it was the right course to pursue it summarised pre-existing knowledge and provided both a foundation and a framework for future work, and some of the most important and fundamental of Haeckel's ideas have stood the test of time Thus he divided living beings into Animals, Plants and Protista , regarding the last group, which included the simple unicellular organisms, as the common seed-bed from which both animals and plants have sprung The discovery of green ciliates like some species of *Stentor* and *Vorticella*, and of colourless carnivorous Dinoflagellates which devour young oysters, in addition to the ordinary brown species which live like brown seaweeds, has more than justified Haeckel's classification

Haeckel's most far-reaching hypothesis was, however, his famous 'biogenetic law' He invented the terms phylogeny and ontogeny—the first, according to him, designated the palæontological history of the race, the second the history of the development of the individual from the egg to the adult condition The law connecting these two was the 'Biogenetic fundamental principle' stated in his own words, it ran thus "Ontogeny is a short and quick repetition, or recapitulation of Phylogeny determined by the laws of inheritance and adaptation" Haeckel pointed out that if this principle be admitted, there is some hope of tracing, in outline at least, the actual course of evolution , whereas if we were to confine ourselves to palæontological evidence, we should only see glimpses of evolution in special cases The past history of the Vertebrata may be traced from fossils with considerable exactitude since vertebrates possess an internal skeleton which is often preserved and which gives in its scars and processes, evidence of the muscles which once accompanied it and consequently of the actions and habits of the animal which possessed the skeleton The external skeleton of extinct Crustacea which clings tightly to every protuberance of the body, also reveals a good deal about the activities of its former possessor But what scanty light do the shells of extinct Mollusca and the tests of ancient Echinoderms throw on the internal structure of their owners ! Who would dream from their evidence that radiate Echinoderms were derived from bilateral ancestors ?

In our judgment the formulation of this biogenetic law was the greatest service which Haeckel did to the science of zoology, and the more we reflect on it the greater the service will appear Haeckel was, of course, aware that these reminiscences of ancestral life could be modified, blurred or occasionally completely obscured He knew that for the elucidation of life-histories only the comparative method would avail , and just as in the comparison of two ancient documents the truth will shine through the errors peculiar to each one, so with life-histories

The acceptance of this law as giving a picture of evolution drew with it certain conclusions as to the causes of evolution. Haeckel described variations as 'adaptations' There were, he said, two classes of these, namely, (1) small ones which were the result of habits and which were *transmitted to posterity with greater certainty the longer they had lasted* (this is pure Lamarckian doctrine), and (2) great adaptations which appeared suddenly and the causes of which were unknown to us, though in some cases they appeared to have originated with intra-uterine influences These latter are now, of course, called mutations, and it was the first category alone which Haeckel believed to be significant for evolution, for the growth of the individual suggests that evolutionary growth was slow, functional and continuous

The biogenetic law proved a tremendous stimulus to zoological research Of course, it encountered opposition , its enthusiastic votaries desired, like all enthusiasts, to reach the 'promised land' at once they failed to realise that ancestral history could only be elucidated by prolonged, careful and comparative research They could not deny themselves the pleasure of making wild guesses as to ancestry based on the study of some one life-history and in time 'Haeckelismus' became a term of reproach But the principle was essentially sound , from all opposition it emerged triumphant it has been transferred to ever wider fields and has been found to throw light even on the development of the mental life of man A certain school of biologists at the present day affects to denigrate it and that for obvious reasons, for if it is sound then one thing is certain, mutations have played no part in evolution But ancestral history stands out so clearly in some life-histories that none but the wilfully blind can deny its presence Amongst the Ctenophora, for example, there are two aberrant forms, *Tjafiella* and *Cœloplana* The first resembles a sponge, the second a flat-worm , yet both begin their free existence as typical little Ctenophores, globular in form with 8 meridional bands of cilia radiating from the upper pole But if ancestral history is the foundation of some life-histories is it not reasonable to assume that it lies at the base of all ?

The real originator of the theory that evolution proceeded by jumps and that "Discontinuity in variation was the cause of discontinuity in species" was the late Dr Bateson In his first and best work on the development of *Balanoglossus* he found himself driven to the conclusion that Echinoderms and Vertebrates had radiated from a common stock and his faith in 'recapitulation' failed him, although it is interesting to record that this conclusion has been sustained by recent research and that from the most unlikely quarter, namely, biochemistry He then made "*il gran rifiuto*" and fell back on sports and monstrosities as the material of evolution. At the meeting of the Zoological Congress in Cambridge in 1898, Bateson put forward his views Haeckel was present at the meeting and some sentences of his still linger in our memory. He said that if views like these are to be accepted, "Kehren wir lieber zu Moses zuruck"

Prehistoric and Primitive Surgery

THE Vicary lecture before the Royal College of Surgeons was delivered on December 8 by Dr. L W G Malcolm, conservator of the Wellcome Historical Medical Museum, who chose as his subject "Prehistoric and Primitive Surgery"

The surgery of prehistoric and primitive times cannot be treated on rational lines when it is considered in time and space There is all the difference in the world between the ideas of primitive man and those of the founders of rational medicine and surgery—the Greeks. It does not appear that there is any community of ideas in the primitive world unless considered from the ritualistic point of view

Omitting for the most part reference to prehistoric Europe, to which detailed attention, especially in regard to trephining, has been paid by Dr. Wilson Parry, the available evidence shows that certain major operations have been performed by the prehistoric and primitive surgeons, involving a greater or less degree of skill and knowledge of anatomy, but such methods of treatment as bandaging, poulticing, lancing, bone-setting and the rarer amputation, massage, especially in relation to child-birth, cupping and bleeding, blistering and cauterising, fomentation and the vapour-bath were more or less common knowledge of the tribe, as the product of a real, if perhaps uncritical, experience

The leechcraft of the professional medicine-man, or shaman, is in a different category Although he has a knowledge of everything the lay medicine-man may practice, he is able to control the basis of magic, the universal power or soul-*mana*. Magical therapeutics may be traced from the earliest times down to the present day. The magical ritual had an accompanying expression in some therapeutic measure, for example, blood-letting or massage When a medicine-man, for example, trephined a head, he was performing a rite to satisfy the religious beliefs of the tribe, but as the tribe progressed in knowledge, the ritual process was abandoned and an allegorical object substituted as an offering to the god Thus a gourd with a hole in it was offered to the god, who accepted it as a trephined head in lieu of the actual operation.

Turning to the rational surgery of primitive and prehistoric peoples, trephining of the skull was practised by the pre-Columbian inhabitants of Peru, the methods employed falling into four groups: scraping, sawing, cutting, and drilling, the last being rare The objects of the operation were to treat a depressed fracture, such as might be caused by a sling-shot, to relieve pain or for superstitious reasons. The evidence on the whole does not support the use of a plate to fill the hole, or of suture. The operation is reported to-day, especially in North Africa, Polynesia, India and Peru

The lesion now known as the sincipital T is found on skulls from the dolmens near Nantes in France It takes the form of a long antero-posterior groove along the sagittal suture, terminating near the obelion where the transverse branch is encountered It has been recorded among the ancient Canary Islanders as due to the cauterising of a scarification with a flint knife, and a similar lesion has been found in a pre-Columbian female skull from Peru In the Middle Ages this operation was performed on demented individuals, usually female, to allow the application of heated objects to the skull It reduced "the amount of cold humours in the head".

The disease uta, a phase of leishmaniasis, has left traces on certain skulls from South America The primitive surgeon would appear to have amputated the diseased part of the face in one example The effects of this treatment are represented in the realistic Peruvian prehistoric pottery

In major surgical operations, the most astounding is the Cæsarian operation performed by a native of Uganda in 1879 The wound healed entirely on the eleventh day A similar operation has been recorded among the Chippeway Indians, but without detail. Ovariotomy is said to be performed in India and among the aborigines of Australia, but exact evidence is lacking. Although the Aztecs and Incas must have acquired a knowledge of anatomy from the practice of extracting the heart from the living sacrificial victim, they do not seem to have been led thereby to perform operations on the internal organs

Hernia was treated among the Pueblo Indians of America by the use of pads and bandages, and the Basket-makers used a flattish oval pad This was worn by new-born infants by means of long strings to prevent umbilical hernia Umbilical hernia is extremely common among primitive peoples, especially in Africa, but they do not appear to do anything for it

From the prehistoric pottery it would appear that the Incas performed some remarkable operations on the limbs. The cliff-dwellers of North America, who suffered severely from fractures, were skilled in the use of splints for thigh and arm, a purpose for which the Aztecs used the leaves of the century plant, moist clay serving as a cast. The aborigines of South Australia coat the fractured limb in a kind of plaster of Paris. Among the North American Indians, manipulation and particularly traction, manual and mechanical, were employed in the reduction of dislocations Relaxation was produced by the use of stramonium, alcohol, infusions of tobacco and other drinks.

Three methods of blood-letting are practised by primitive peoples: suction, scarification and venesection. Ingenious methods of venesection were employed. One found among the Indians of the Isthmus and Brazil was to shoot a stone-headed arrow into the vessel. This method is also found in New Guinea. Venesection is employed in the armpit, the forehead, the vertex and various other parts of the body. In Peru the veins at the root of the nose were opened The use of the cupping vessel is widespread.

The stopping of a blood-vessel presents difficulties, but the methods employed are amazing in their variety, including powdered gum, charcoal, ashes, eagle's down, bandages of bark, coconut fibre, etc A kind of tourniquet of bark cloth is recorded in Loyalty Islands, Tahiti, Samoa and Tonga The prevalent method of cleansing wounds among the American Indians was by sucking out the pus, a method which gave the shaman opportunity to display his magic power by showing a pebble which he had sucked from the wound

While it has been shown from the examples quoted above that the primitive peoples of America had a certain idea of rational surgical procedure, the remainder of the primitive world, with few exceptions, did not exhibit the same degree of surgical appreciation The races and tribes of Africa who practise an advanced procedure have derived their knowledge from other races—all tribes south of the Sahara, for example, have been influenced by Arabian surgery. There is, however, a remarkable number of mutilations which involve a certain knowledge of surgery. These are usually ritualistic in origin, such as circumcision (male and female) and infibulation There are no less than fourteen different methods of operating on the male genitalia employed in various parts of the primitive world. Among other forms of mutilation is amputation of the fingers, which was practised by the Aurignacian peoples of palæolithic times and is recorded by imprints on rocks in California, Arizona, Peru, Africa and Australia. Cicatrisation is also a sacrament Other mutilations in a variety of forms are practised on the nose and cheeks Piercing the tongue is not common, but excision of the tongue is practised in West Africa

A review of the subject leads to the belief that the resistance of primitive people is abnormal, compared with that of modern civilised races Their apparent indifference to pain and the infrequency of blood-poisoning indicate that modern races pay for their civilisation in terms of lessened resistance, pathology and neurology

The lecturer expressed his acknowledgments to Dr R Moodie and Dr L Freeman

Artificial Production of a New Kind of Radio-Element

By F JOLIOT and I CURIE, Institut du Radium, Paris

SOME months ago we discovered that certain light elements emit positrons under the action of α-particles[1] Our latest experiments have shown a very striking fact. when an aluminium foil is irradiated on a polonium preparation, the emission of positrons does not cease immediately, when the active preparation is removed The foil remains radioactive and the emission of radiation decays exponentially as for an ordinary radio-element We observed the same phenomenon with boron and magnesium[2] The half life period of the activity is 14 min for boron, 2 min 30 sec for magnesium, 3 min. 15 sec for aluminium

We have observed no similar effect with hydrogen, lithium, beryllium, carbon, nitrogen, oxygen, fluorine, sodium, silicon, or phosphorus Perhaps in some cases the life period is too short for easy observation

The transmutation of beryllium, magnesium, and aluminium α-particles has given birth to new radio-elements emitting positrons These radio-elements may be regarded as a known nucleus formed in a particular state of excitation; but it is much more probable that they are unknown isotopes which are always unstable.

For example, we propose for boron the following nuclear reaction:

$$ {}_5B^{10} + {}_2He^4 = {}_7N^{13} + {}_0n^1 $$

${}_7N^{13}$ being the radioactive nucleus that disintegrates with emission of positrons, giving a stable nucleus ${}_6C^{13}$. In the case of aluminium and magnesium, the radioactive nuclei would be ${}_{15}P^{30}$ and ${}_{14}Si^{27}$ respectively

The positrons of aluminium seem to form a continuous spectrum similar to the β-ray spectrum. The maximum energy is about 3×10^6 e v As in the case of the continuous spectrum of β-rays, it will be perhaps necessary to admit the simultaneous emission of a neutrino (or of an antineutrino of Louis de Broglie) in order to satisfy the principle of the conservation of energy and of the conservation of the spin in the transmutation.

The transmutations that give birth to the new radio-elements are produced in the proportion of 10^{-7} or 10^{-6} of the number of α-particles, as for other transmutations With a strong polonium preparation of 100 millicuries, one gets only about 100,000 atoms of the radioactive elements Yet it is possible to determine their chemical properties, detecting their radiation with a counter or an ionisation chamber. Of course, the chemical reactions must be completed in a few minutes, before the activity has disappeared.

We have irradiated the compound boron nitride (BN) By heating boron nitride with caustic soda, gaseous ammonia is produced The activity separates from the boron and is carried away with the ammonia. This agrees very well with the hypothesis that the radioactive nucleus is in this case an isotope of nitrogen.

When irradiated aluminium is dissolved in hydrochloric acid, the activity is carried away with the hydrogen in the gaseous state, and can be collected in a tube The chemical reaction must be the formation of phosphine (PH_3) or silicon hydride (SiH_4) The precipitation of the activity with zirconium phosphate in acid solution seems to indicate that the radio-element is an isotope of phosphorus

These experiments give the first chemical proof of artificial transmutation, and also the proof of the capture of the α-particle in these reactions[3]

We propose for the new radio-elements formed by transmutation of boron, magnesium and aluminium, the names *radionitrogen*, *radiosilicon*, *radiophosphorus*

These elements and similar ones may possibly be formed in different nuclear reactions with other bombarding particles protons, deutrons, neutrons For example, ${}_7N^{13}$ could perhaps be formed by the capture of a deutron in ${}_6C^{12}$, followed by the emission of a neutron

Obituary

SIR DONALD MACALISTER, BART, K C B

BY the death at Cambridge on January 15 of Sir Donald MacAlister of Tarbert, in his seventy-ninth year, a great personality has passed out of the academic and medical life of Great Britain He was a Scottish highlander descended from the MacAlisters of Tarbert in Argyllshire, a family which for about five centuries possessed considerable lands in Kintyre and the heads of which were hereditary keepers of Tarbert Castle. Although originally a branch of the great clan MacDonald, they held their Tarbert possessions in charter from the Campbells with whom they cast in their lot in politics and war

Sir Donald MacAlister was born in Perth on May 17, 1854, and received his school education there and in Aberdeen and Liverpool, the changes in family residence being necessitated by his father's business activities In 1873 he entered St John's College, Cambridge, and in 1877 was senior wrangler and first Smith's prizeman in addition to receiving many other University distinctions A year later he was elected a fellow of his college and having meantime turned to the study of medicine he graduated M B in 1881 and M.D in 1884 Settling in Cambridge as a consulting physician, he was appointed Linacre lecturer on physic and a member of the staff of Addenbrooke's Hospital and thus became actively engaged in medical teaching His earliest professional studies had been in the domain of pathology, but this was soon superseded by pharmacology and therapeutics, subjects in which he retained a keen and active interest to the end. In recognition of his special attainments he was chosen president of the Section of Therapeutics at the Toronto meeting of the British Medical Association and for many years was chairman of the "British Pharmacopœia" Committee, the 1898 and 1914 editions of which owed a great deal to his collaboration

Although deeply interested in scientific and medical research and keenly appreciative of their results, Sir Donald MacAlister was never a 'research worker' in the ordinary sense of the term His cast of mind and abilities were more those of the statesman and administrator and it was in these directions that he found a congenial field for his activities and that he reached his highest distinction. In Cambridge he took a large share in the administrative work of the University and in 1889 was elected its representative on the General Medical Council He soon became one of its most influential members and when he resigned from it last year on account of failing health, he had served for forty-four years, twenty-seven of which were in the presidential chair As president his advice was frequently sought by the Privy Council and other Government departments concerned with the administration of medical education, pharmacy and the public health, and in these matters he gradually came to exercise a far-reaching influence

It was, however, not in medical matters only that Sir Donald MacAlister's influence on higher education and its administration was felt His exceptionally wide knowledge and culture rendered him highly sympathetic to all the many departments of university studies and activities, this led to his being chosen chairman of the Universities Bureau of the British Empire, chairman of the Commission on the University of Belfast, and to much other similar public work In 1907 he was appointed by the Crown to the high office of Principal of the University of Glasgow and shortly thereafter was made K C B In 1924 he was created a baronet in recognition of his many public services. When he went to Glasgow he had no special acquaintance with Scottish university affairs, but in a surprisingly short time he had acquired a complete grasp of them no less in their business than in their teaching aspects, and this soon found expression in numerous changes and reforms During his principalship he inspired such confidence in the citizens of Glasgow that money was freely forthcoming for the establishment of many new chairs and lectureships and for general university expansion. Nor were the social and athletic sides of student life overlooked A new Union costing £65,000 was built, new playing fields were provided and three residential halls for men and one for women were acquired by the University. From many contributors he received personally a large sum of money which was devoted to the building of a chapel in memory of those members of the University who perished in the War, and this will ever remain a beautiful memento of his principalship.

Besides being the recipient of honorary academic degrees too numerous to mention in detail, Sir Donald MacAlister was decorated by the French and Italian Governments, and from his fellow-citizens he received the freedom of the city of Glasgow in recognition of his great services to their University and in testimony of their personal esteem. In 1929 he resigned the principalship after twenty-two years service and was unanimously elected Chancellor of the University in succession to the late Earl of Rosebery and Midlothian His success as an administrator was largely due to an inborn aptitude for affairs, to a retentive memory for details and to a clear conception of the objects to be attained, but these were greatly enhanced by his industry, his devotion to duty and, as time went on, his wide experience

WE regret to announce the following deaths

Prof. H. L. Chablani, professor of economics in the University of Delhi, on January 14, aged forty-four years

Prof Fritz Haber, formerly director of the Kaiser Wilhelm Institute for Chemistry and professor of physical chemistry in the University of Berlin, known for his work on the thermodynamics of gas reactions, on February 1, aged sixty-five years.

Dr William Page, general editor of the "Victoria History of the Counties of England", and a commissioner of the Royal Commission on Historical Monuments (England), on February 3, aged seventy-two years

Capt J White, C B, R N, formerly dean of the Royal Naval College, Greenwich, previously professor of applied mechanics at the College, on January 28, aged sixty-three years.

News and Views

"Letters to the Editor"

DURING the year 1933, no less than four hundred communications appeared in NATURE under the heading of "Letters to the Editor", the big majority of which were the first announcements to be published of new work—news from the actual contributors to advances in science. Of this total, 201 were from scientific workers in universities and similar research centres in Great Britain and Ireland, and the remainder, 199, were from workers abroad distributed by continents as follows. Europe 78, America 57, Asia 37, Australia 14, Africa 13. In this week's issue of NATURE we are devoting 20 columns to 'letters' and the size of the journal has been increased to provide the necessary space. These 20 columns are, we believe, representative of the correspondence normally appearing in NATURE. The various items record current advances in biochemistry, atomic physics, radio communication, chemistry, biology and so on, and they are written by workers in Allahabad, Cambridge, Copenhagen, Dehra Dun (India), Groningen, Liverpool, London, Maine (U.S.A.), Nanking, Oxford, Schenectady, Stockholm, Sydney and Uppsala. Science truly is not confined by national boundaries. We think it a high compliment that scientific workers all over the world should regard our columns as the appropriate place to announce the progress of their labours and to discuss scientific matters and topics in which science and its methods are involved.

THIS part of the function of NATURE as an international journal of science has increased steadily in recent years. For some time past, the section of the journal devoted weekly to "Letters to the Editor" usually occupies 12 columns and frequently has been increased to 14 columns or more. Already this year we have printed 88 columns of 'correspondence', including the 20 columns appearing in this issue. Yet the waiting list is still large. The amount of space which can be given to 'letters' in a normal issue of NATURE must of necessity be limited if the journal is to discharge the remaining part of its function as a general journal of science, and we may even be obliged in the future to ask correspondents to limit their 'letters' to about five hundred words, or one column of space. For the present, we would urge them most strongly to be concise and precise in their communications, so far as is consistent with making them intelligible to the general reader A certain amount of specialised matter is inevitable in announcements and discussions, particularly of recent advances, but severely technical communications, of interest to a few workers only in the same highly specialised field, are out of place in a general journal such as NATURE, which endeavours to keep its readers informed of the broad lines of progress in all scientific subjects.

Dr. C. V. Drysdale, C.B., O.B.E.

DR C. V DRYSDALE, director of scientific research at the Admiralty, whose impending retirement is announced, has long been recognised as an authority on electrical measurements. In the early part of this century, while in charge of the Electrical Engineering Department of the Northampton Polytechnic Institute, he devoted considerable attention to measurements in the alternating current circuit, and his work on the dynamometer wattmeter, and particularly the development of the double element instrument for the measurement of polyphase power, is now well known. This was followed by several important contributions to technical literature on alternating current measurements, and included his pioneer work on the design of instrument transformers. The regenerative dynamometer together with the cone stroboscope were also devised at about this time for the equipment of the laboratories He also investigated the possibilities of using iron cores in dynamometer instruments and had some of the first iron-cored wattmeters built to his design which gave remarkably good performance. The simple phase shifting transformer was also designed and built, being originally intended to facilitate testing the performance of wattmeters at low power factors, and eventually this apparatus made possible his adaptation of the direct current potentiometer to the measurement of alternating potentials. This was the first self contained instrument for this purpose, and in connexion with it he designed the first vibration galvanometer with tuning effected by variation of the magnetic control. He also gave considerable attention to accurate resistance measurement and devised a new form of standardising bridge which was a combination of the Kelvin and Carey Foster principles, and allowed of precise comparisons between standards over a wide range of values to be made with great accuracy and rapidity, and in connexion with this bridge he developed a novel and accurate ohm standard ingeniously compensated for temperature change. Some time later he designed low resistance standards with very small time constants for use in alternating current circuits.

DR. DRYSDALE'S activities were not, however, entirely confined to work in electrical measurements, for at one time he gave considerable attention to the testing of magnetic materials and investigated the rotary hysteresis in iron and steel and developed an ingenious permeameter for testing magnetic materials in bulk. He also contributed papers on the radiation from black-bodies and made some important determinations of the mechanical equivalent of light which were communicated to the Royal Society. To him also belongs the credit of initiating the teaching of technical optics, in what is now the Technical Optics Department of the Northampton Polytechnic Institute, and into this work he carried the same enthusiasm and originality that characterised his electrical work. He devoted much attention to the curvature method of teaching optics and devised many original methods of optical testing and the apparatus for carrying them out. When the War came his services were placed at the disposal of the Admiralty in connexion with submarine detection and destruction, and here his sound theoretical knowledge and brilliant inventiveness found considerable scope and resulted in the appointment from which he is now retiring. Dr. Drysdale is also known as the president of the Malthusian League and as the author of numerous papers on eugenics.

Sir William Preece (1834-1913)

WILLIAM HENRY PREECE, the distinguished electrician, was born at Bryn Helen, Carnarvon, on February 15, 1834. Educated at King's College School and King's College, London, he came under the influence of Faraday at the Royal Institution and, deciding to become an electrician, in 1852 he entered the office of Edwin Clark. The following year he was appointed a junior engineer on the staff of the Electric and International Telegraph Co. and afterwards was telegraph engineer of the Channel Islands Telegraph Co. and the London and South-Western Railway Co., introducing many improvements in railway signalling. In 1870 he joined the staff of the Post Office, becoming in 1892 the engineer-in-chief, a position he held until 1899. His work in telephony began in 1877 and it was he who brought to England the Bell telephone with which Kelvin and Haughton gave an amusing demonstration at the Plymouth meeting of the British Association that year. As much scepticism existed regarding the capacity of the telephone, Preece arranged for the transmission of the notes of a bugle from Southampton to the Royal Institution during a lecture he delivered. A large and distinguished audience was present and at the appropriate moment Preece asked Tennyson to listen at the telephone. After doing so for a few moments, the poet remarked gruffly, "I hear nothing." Preece, catching up the telephone, after adopting a listening attitude, said, "I can hear, 'The Campbells are Coming' ", and then proceeded with his lecture, none in the audience realising that the bugler had mistaken the date, and that Preece himself, like Tennyson, had heard nothing.

PREECE'S work on telephony led him in 1885 to make experiments on induction signalling and in 1892 he sent messages across the Bristol Channel from Penarth to Flat Holme. His work in this direction came to an end, however, with the use of the Hertzian waves. "Strange to say," wrote Silvanus Thompson, "he entirely missed the significance of the wireless signalling by Hertzian waves shown by Lodge at the British Association meeting at Oxford in 1894, and yet when Signor Marconi arrived upon the scene in 1896 using the same method and the same devices of oscillators, spark gaps, coherers and tappers, Preece received him with open arms and put the resources of the Post Office at his disposal with results known to all the world." By the time Preece retired three years later, wireless messages were being sent across the English Channel and between some of H.M. ships. Preece, who was admitted F.R.S. in 1881, twice served as president of the Institution of Electrical Engineers and in 1898 was elected president of the Institution of Civil Engineers. He was knighted on his retirement and was afterwards consulting engineer to the Colonies. His death took place at Penrhos, Carnarvon, on November 6, 1913.

Russian Ascent into the Stratosphere

SYMPATHY will be felt for the three Russians, Fedoseenko, Vasenko and Usyskin, pilot, engineer and student respectively, who met their deaths on January 30 in an attempt to investigate further the phenomena of the upper atmosphere. It was announced in the Press that a new height record of about 70,000 ft. had been established for a manned balloon, a conclusion arrived at from the record of the damaged barograph. The pressure reached, however, has not yet been published. Apparently the accident was due to heavy weather as the prime cause, for it appears that the balloon travelled about 350 miles in a south-easterly direction from Moscow in the first four or five hours of its flight. Two of the occupants were unwell and in dropping rapidly through cloud, the collection of ice on the gondola, together with that falling on it from the lower part of the balloon structure itself, and other chafing actions, eventually parted the gondola from the balloon. The chief object of the flights, organised by the Society for Aviation and Chemical Warfare, was to investigate cosmic rays and it has been said that thirty instruments for various purposes were being carried The balloon expanded had a diameter of 115 ft and the whole weighed 2 tons The metal parts were of rustless steel The lowest pressure record of 50 mm (61,000 ft) for a balloon rests at present with the stratostat *U S S R* piloted by M Prokofiev last September

Photographs and Early Maps of the Fenland of East Anglia

IN the Art Gallery of Messrs W. Heffer and Sons, Ltd, Cambridge, there is an exhibition of ancient maps of the Fenland and of recent aerial photography of the same region. This exhibition, which will be open until February 12, directs attention to the activities of the organising body, the Fenland Research Committee, which was founded under the presidency of Prof A C Seward in 1932, for promoting the intensive investigation of the complex history of the Fenland basin The members represent the interests of archæological, botanical, geological and historical science, co-operating closely in attacking the very complex problems of the developmental history of the Fenland basin Co-ordinated excavations have already been made and a number of publications have appeared One extremely important side of the work of the Committee is the aerial photography of the entire region. This reveals on the silt area of the fens beside the Wash a hitherto unsuspected density of remains of the Romano British occupation and of later times Field systems, *dwellings, river-beds, droves and creeks are visible* in great profusion and clarity, and the examination, interpretation and mapping of these remains will be a major activity of the Committee for some time to come The preparation of suitable field maps for use in this task is a heavy charge on the Committee and the exhibition is intended to stimulate public assistance to the provision of part or all of the sum of £500 required

Beam Wireless Communication with China

ON February 3 a new Marconi beam wireless station was opened at Chenju, near Shanghai, to give direct radio communication with Great Britain, and it is anticipated that within the next year Shanghai will be in telephonic communication with London. This will add yet another link to the already widespread ramifications of the international radio telephone service available from London. In announcing the opening of the new station, the *Times* recalled the fact that the first wireless station in China was erected by that journal at Wei-hai-wei in 1904 in order to receive dispatches during the Russo-Japanese war from its correspondents on board a steamer specially chartered for the purpose. The Marconi Co later undertook the establishment of communication for the Chinese Government, and the recent extension referred to above is due to the enterprise of the Ministry of Communications The whole of the technical material used for the Chenju station was purchased in Great Britain with funds from the British Boxer indemnity, and Chinese engineers have co-operated most effectively in the installation.

Electric Discharge Lamps

SOME interesting characteristics of the new electric discharge lamps were described and demonstrated in a lecture given before the North-West Area Section of the Illuminating Engineering Society at Manchester on January 30 by Mr H. R. Ruff, of the Research Department of the British Thomson Houston Co, at Rugby. Mr. Ruff showed that highly coloured wall papers are completely robbed of their colour by a form of lamp using sodium vapour, appearing as though executed only in black, white and grey On the other hand, an electric discharge lamp using mercury vapour was shown to contain strong yellow, green and blue elements—with the result that coloured papers show up quite well by this light Numerous installations of these lamps are being made in streets throughout Great Britain, and they are also proving to have interesting possibilities for use in factories A certain amount of care is, however, necessary when applying them to processes with revolving machinery, owing to the formation of stroboscopic effects, by which wheels appear to be turning in a contrary direction These lamps provide about 16,000 lumens for a consumption of 400 watts and can be adapted to ordinary supply circuits using either alternating or direct currents, although the former is more convenient. The efficiency is 2½ 3 times that of a filament lamp A new form of vacuum lamp containing mercury which emits a moderate amount of ultra-violet light and is thus useful from the hygienic point of view was also shown

Constitution of the Upper Atmosphere

PRESENT conceptions of the physical and chemical constitution of the upper atmosphere were summarised in a most entertaining way by Dr G C Simpson in the twenty-fourth Bedson lecture delivered at Armstrong College, Newcastle-upon-Tyne, on February 2 Dr Simpson dealt first with the thickness of the troposphere over the earth's surface, and the temperature distribution within it, and throughout the stratosphere, including the discoveries of Lindemann and Dobson since 1920 from observations of meteors, also ozone concentration and distribution relative to (surface) atmospheric pressure. The evidence of sound wave and wireless wave reflections was then reviewed, and finally the evidence from auroral observations on the influence of sunlight, and on the composition of the atmosphere. Clouds in the stratosphere, and the dissociation of oxygen and nitrogen molecules at 100 km and above were all touched upon. Throughout his lecture, Dr. Simpson stressed the uncertainty of prophecy in these matters, but his exception of weather forecasting caused amusement Most of the learned societies of the district were represented in the audience, which was highly appreciative of the visit.

Neon Signs

THE discharge tubes used for advertising are a development of the old Geissler and Crookes tubes in which various beautiful effects were produced when evacuated tubes filled with certain gases were excited by an induction coil. In the January Engineering Supplement to the *Siemens Magazine*, there is an interesting article on the construction and the physical theory of commercial discharge tubes by E. A Beavis Forty years ago, the gases used were mostly nitrogen and carbon dioxide, and these required continual replenishing It was only when the rare gases, argon, neon, helium, etc , were experimented with that it was found possible to obtain a reasonably permanent luminous discharge These gases are not subject to absorption to anything like the same extent as the commoner gases Neon at a suitable pressure gives more visible light and has a lower electrical resistance than the other permanent gases and hence a greater length of tubing can be operated for a given voltage Neon has a cheerful red glow, argon gives a faint lavender colour and has little luminosity, and helium has a whitish glow Combinations of various gases and vapours with neon and the use of coloured glass tubes have enabled many striking and pleasing coloured effects to be obtained The positive column extending to the anode forms the main region of luminosity in the tube By mixing traces of impurity in the gas, it is possible to obtain narrow cords of light which move within the tube and give rise to the type of discharge known as the 'ripple neon' Sometimes also the column of light splits up into rows of coloured discs which often rotate round the axis of the tube These effects are known as 'striations' Alternating current is used for operating commercial tubes. As the voltage absorbed under running conditions is about 200 volts per foot of tube, it is usually divided up into a number of sections each supplied by a separate transformer

Banting Research Foundation, Toronto

THIS foundation arose out of the desire to commemorate the discovery of the active principle of the islets of the pancreas by Dr. F. G. Banting in 1921-22, and has received wide financial support in Canada. It has now been in active operation for six and a half years, though in the first two years the full capital sum was not available and the number of grants made were few. The capital sum now amounts to about 700,000 dollars and the number of individual grantees has steadily increased The total number of grants made during the period is 92. These have been distributed to 63 workers in the following universities: Alberta 4, Saskatchewan 2, Dalhousie 8, Queen's 2, Western Ontario 2, Manitoba 16, McGill 26, Toronto 30 and 2 non-university. Some fifty papers have already appeared in scientific publications, while a further fifteen are in press or ready for publication. Several pieces of work are not as yet complete. In accordance with its charter, the Foundation also aids in the support of the Department of Medical Research, University of Toronto (Dr. F. G Banting) and from this source numerous papers on silicosis, the action of vitamins and other topics have appeared During the past year twenty workers received grants from the fund. The Foundation, which is the only one in Canada giving support to medical research, has proved a valuable aid and stimulus to such research in that country The world economic depression has increased the demands upon the Foundation, the trustees of which would welcome a larger revenue. Correspondence should be addressed to the Banting Research Foundation, Toronto, Canada

Reptile Skins in Commerce

A FEW years ago the use of the skins of reptiles in the manufacture of shoes was regarded as a whim of the moment, but now the view is strongly held by the leather trade and by technical experts in the industry that the skins are established as a raw material for leather production on as permanent a basis as goat, calf and sheep skins This is the view expressed by the sub-committee appointed by the Imperial Institute Advisory Committee on Hides and Skins (*Bull Imp. Inst*, 31, No 2, 160, 1933) The change in outlook has taken place since 1926, when reptile skins were employed only in the making of luxury articles, now they are used for the mass-production types of shoes, as well as for bag and fancy leathers. Some of the advantages of reptile leather are that it is hard-wearing, stronger than sheep, goat or even calf skins, it shows great variety of pattern and design, and it takes colour readily But the demand has been telling upon reptile populations in various tropical countries In 1932, India exported 2½ million reptile skins, in 1931, more than two million came from the Dutch East Indies, and serious depletion has occurred in the stock of the North American alligator, the edible terrapins of the United States, and the green turtle, the last being valued as food An exhibition of reptile skins and their products will be opened at the Imperial Institute on February 12 at noon by Lieut.-Col J Colville, Parliamentary Secretary to the Department of Overseas Trade

Eton College Natural History Society

IT is encouraging to find that in the public schools of Great Britain there is no sign of declining interest in field studies. The expeditions held on holidays and half holidays by the Eton College Society are excellent as introductions to natural history, and may lead to the more individual interest which is revealed in the lists of records, of lectures, and of museum preparations mentioned in the annual report for 1932-33. The report is enlivened by photographs taken by the members, and a list of Lepidoptera from the Eton district, by Brigadier-General B. H. Cooke, should be useful as a check-list for youthful collectors.

Destructive Earthquakes in 1933

SCIENCE SERVICE, Washington, D.C. (Mail Report, December 28, 1933) has issued a list of 39 earthquakes in 1933 that were strong enough to be recorded by distant seismographs. Of these, only five caused the loss of many lives. The most destructive was the Sanriku (Japan) earthquake of March 3, by which 1,560 persons were killed in addition to 956 others missing. The Long Beach (California) earthquake of March 10 was responsible for the loss of about 120 lives, the Kos earthquake of April 23 for about 100, the West Sumatra earthquake of June 24 for about 70, and the Chinese earthquake of August 25 for about 100. The Baffin's Bay 'earthquake' of November 20 would no doubt have added to the number had it not occurred in an uninhabited region. The total number of persons killed by earthquakes in 1933 is thus less than 3,000, or less than one-half the number killed on the roads in Great Britain, and much less than the average number (about 14,000) killed by earthquakes every year (NATURE, 126, 214; 1930).

Early Students' Laboratories

WHEN Lord Kelvin opened the laboratories of University College, Bangor, in 1885, he gave an address on scientific laboratories which was printed in NATURE of March 5, 1885, p. 409. He stated that the physical laboratory he started in an old wine cellar in the University of Glasgow on his appointment as professor of natural philosophy in 1845 was the first one intended for students' practical work, and that the first chemical laboratory for a similar purpose was that of Prof. von Liebig at Giessen, founded "not many years after 1831". In the November issue of the *Review of Scientific Instruments*, Prof. P. C. Ricketts brings forward evidence that both physical and chemical laboratories for the regular use of students were provided at Rensselaer by Amos Eaton when he became professor of chemistry and experimental philosophy there in 1824, and that "the instruction was extremely systematic and continuous".

Microscopes and their Accessories

WE have received from Messrs. W. Watson and Sons, Ltd., 313 High Holborn, London, W.C.1, a copy of the new edition of their microscope catalogue. A number of microscope stands of varying complexity are listed, and ranging in price from £4 to £100, together with ranges of objectives, eye-pieces, sub-stage fittings, etc. Several pages are devoted to a description of the principles of construction adopted by Messrs. Watson. The limb, carrying the body at one end and the sub-stage at the other, is machined from a solid casting, ensuring basic alignment throughout, and that the stage bracket is truly at right-angles to the body and sub-stage. Similarly, the tube, rib and objective fitting are machined from a solid metal billet, instead of being in three pieces as formerly, so that the risk of separation of parts is abolished, and enduring parallelism between the mechanical and optical axes is ensured. Water immersion objectives, a new low-power binocular, and new dark-ground condensers also find a place in the catalogue.

Plan for Exploring Soviet Far North in 1934

AT a recent session of the Scientific Council of the All-Union Arctic Institute, plans were adopted for expeditions to the far north during this year. The plans include extensive exploration of the great northern sea route. The *Moscow Daily News* reports that particular attention is to be paid to the little-known Laptev and Eastern Siberian seas. Geological expeditions will aim at creating a fuel base for ships navigating the great northern sea route and at discovering ores of non-ferrous and rare metals. Their attention will therefore be concentrated on Novaya Zemlya, the eastern part of the Chukotsk peninsula and Northern Land, where indications of oil, coal and ores have been found. Geodetic expeditions with an aeroplane at their disposal will carry out preparatory work for compiling the first 1 : 1,000,000 map of the Soviet Arctic, to be published in 1937. Five new permanent research stations will be added to the existing twenty, and a new laboratory for the study of magnetic phenomena will be erected near the estuary of the Kolyma. Attention is to be paid to the study of reindeer and polar dog breeding. Special breeding farms are to be organised in order to facilitate communication between the stations along the northern sea route.

Pumps at the Science Museum

THE plan now being followed at the Science Museum, South Kensington, is to publish handbooks of two kinds, one containing historical notes, and the other containing details of the exhibits. Some time ago we directed attention to the new volume of "Historical Notes on Pumping Machinery" and we now have pleasure in referring to the new "Descriptive Catalogue". Like the former, this has been prepared by Mr. G. F. Westcott. The notes placed alongside the exhibits in the Science Museum have long been known for their fullness and their accuracy, and the "Descriptive Catalogue" contains more than five hundred of these notes together with many excellent illustrations. The pumping machinery collections are divided into about twenty groups and the exhibits range from the most primitive baling appliances to large turbo-blowers and the mercury vapour vacuum pumps of Gaede and Langmuir. The price of the new volume is 3*s*. 6*d*., so that for 6*s*. the reader can obtain both handbooks, which together contain more precise information on pumps of all kinds than can, we believe, be found in any other publication. The compiling of such catalogues involves a very great amount of research and Mr. Westcott is to be congratulated in having brought his task to a successful conclusion.

Medals of the Institution of Chemical Engineers

AT the twelfth annual corporate meeting of the Institution of Chemical Engineers on February 16, presentation will be made of the Moulton medal, the

Junior Moulton medal and prize of books, and the Osborne Reynolds medal, all of which were instituted in 1929. The Moulton medal, which commemorates the chemical engineering work of the late Lord Moulton at the Department of Explosives Supply, is awarded for the best paper of each year presented before the Institution. Papers by non-members of the Institution are eligible for this medal. For 1933 the award is made for the following papers: "The Mechanical Properties of some Austenitic Stainless Steels at Low Temperatures", by Messrs. E. W. Colbeck, W. E. MacGillivray and W. R. D. Manning; and "The Mechanical Properties of Metals at Low Temperatures (2)—Non-Ferrous Materials", by Messrs. E. W. Colbeck and W. E. MacGillivray. The Junior Moulton medal is given for the best paper of the year read before the Graduates and Students Section of the Institution. Only papers by graduates and students of the Institution are considered for this medal and prize. For 1933 the award is made for the paper: "The Solvent Extraction of Sulphur from Sicilian Ores", by Dr. E. H. T. Hoblyn. The Osborne Reynolds medal commemorates the fundamental investigations of the late Prof. Osborne Reynolds, and is awarded for meritorious service for the advancement of the Institution. For 1933 the award is made to Mr. H. W. Cremer. Mr. Cremer acted as honorary secretary of the Institution during the illness of the late Prof. J. W. Hinchley in 1931, and was appointed to succeed Prof. Hinchley in that office on the latter's death.

Announcements

H.R.H. THE PRINCE OF WALES has consented to become patron of the London School of Hygiene and Tropical Medicine, with which is incorporated the Ross Institute.

THE Catherine Wolfe Bruce gold medal of the Astronomical Society of the Pacific for the year 1934 has been awarded to Prof. Alfred Fowler, Yarrow research professor of the Royal Society and professor of astrophysics in the University of London (Imperial College of Science), for his distinguished service in the field of astronomy.

THE council of the Institution of Electrical Engineers has made the twelfth award of the Faraday medal to Sir Frank E. Smith, secretary of the Department of Scientific and Industrial Research. The Faraday medal is awarded either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution. Dr. R. Thury, of Geneva, has been elected an honorary member of the Institution.

MR. C. S. WRIGHT, superintendent of the Admiralty Research Laboratory at Teddington, has been appointed as from July 8 to be director of scientific research, Admiralty, in succession to Dr. C. V. Drysdale.

PROF. HANS FISCHER, professor of organic chemistry and *Privatdozent* in plant physiology in the Bavarian Technical High-school, Munich, will deliver the fourth Pedler lecture before the Chemical Society on Thursday, February 22, at 8 p.m., in the lecture theatre of the Royal Institution. The title of Prof. Fischer's lecture will be "Chlorophyll". Admission to the lecture will be free without ticket.

A CONFERENCE on "Problems of Potato Growing" will be held at the Rothamsted Experimental Station, on Tuesday, February 20, at 11.30 a.m. The chair will be taken by Capt. J. Mollett, chairman of the Potato Marketing Board. Papers on problems in potato cultivation will be read by Drs. G. H. Pethybridge, R. T. Leiper, H. E. Woodman, E. M. Crowther, and Mr. H. V. Garner. Further information can be obtained from the Secretary, Rothamsted Experimental Station, Harpenden.

WITH the issue on January 5, the *Deutsche Medizinische Wochenschrift* entered the sixtieth year of its existence. It contains several important articles, notably one on rheumatic diseases by Prof. Aschoff, and another by Prof. Heine on inflammatory conditions of the iris, with an excellent coloured plate.

A VOLUME of "Abstracts of Dissertations approved for the Ph.D., M.Sc. and M.Litt. Degrees in the University of Cambridge during the Academical Year 1932–1933" (Cambridge University Press, 1933) has been issued, the summaries having been approved by the examiners or by the student's supervisor. By this means, the nature of research work which might otherwise be overlooked for a time is made easily accessible, and copies of the dissertations can be consulted if desired in the University Library or at the University Registry.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An agricultural chemist at the Imperial Institute of Agricultural Research, Pusa—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (Feb. 12). A curator of the Wakefield Museum and Art Gallery—The Town Clerk, Town Hall, Wakefield (Feb. 17). A borough engineer to the Metropolitan Borough of Hackney—The Town Clerk, Town Hall, Hackney, E.8 (Feb. 17). An inspector in connexion with agricultural and horticultural education and research—The Secretary, Ministry of Agriculture and Fisheries, 10, Whitehall Place, S.W.1 (Feb. 26). A temporary veterinary officer to the Lancashire County Council—The Clerk of the County Council, County Offices, Preston (Feb. 28). A bacteriologist and clinical pathologist at Queen's Hospital, Birmingham—The House Governor (March 5). A City bacteriologist to the City Council and professor of bacteriology in the University of Liverpool (joint appointment)—The Registrar, The University, Liverpool (April 14). An assistant in the Museum at the Royal Botanic Garden, Edinburgh—The Regius Keeper.

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Mass Excretion of Œstrogenic Hormone in the Urine of the Stallion

IN earlier investigations[1] it was shown that the largest quantities of œstrogenic hormone (folliculin — s. œstrin) are excreted in the urine of pregnant mares (100,000 mouse units per litre). I found this also to be the case in other equines (ass, zebra) during pregnancy, whereas, in the non-pregnant state, the excretion of hormone both in equines and in other mammals is very small, at most 0.5 per cent in comparison with that of the gravid animal. Curiously enough, as a result of further investigations, it appears that in the urine of the stallion also, very large quantities of œstrogenic hormone are eliminated. (The first determinations indicating the high content of œstrogenic hormone in the urine of the stallion were made by Dr. E. P. Haussler in the scientific laboratory of Hoffmann-La-Roche in Basle.) According to my analyses, the amount of hormone varies between 10,000 and 400,000 m.u. per litre of urine, the differences appear to have some relation to the origin of the animals. 37 litres of urine obtained from four stallions were rendered acid to congo-red by the addition of mineral acid, boiled for five minutes and subjected to exhaustive extraction with benzol. In this way I found a hormonic content of 170,000 m.u. per litre, which can very well be regarded as an average value. The stallion therefore excretes 1,700,000 m.u. of œstrogenic hormone per diem.

These quantities of œstrogenic sex hormone in the urine of a male animal are particularly high when compared with other values as shown in the accompanying table:—

	Per litre (m.u.)	Per diem (m.u.)
Stallion	170,000	1,700,000
Mare	200	2,000
Pregnant mare	100,000	1,000,000
Sexually mature woman	30–200	45–300
Pregnant woman	10,000	15,000

On the basis of my earlier experiments, the urine of pregnant mares is now generally employed as the standard material for the preparation of œstrogenic hormone. The urine of the stallion, which is always procurable, will now also be available as a standard material for the œstrogenic hormone. A stallion produces 62 gm. of hormone in a year.

I found this mass excretion of hormone only in the male and not in the female horse. The determination of the hormone content, therefore, makes hormonic recognition of sex possible in the urine of a horse. In this connexion we find the paradox that the male sex is recognised by a high œstrogenic hormone content. If on examination, only 1 m.u. or even less hormone is found in 1 c.c. of horse's urine, the feminine sex may, as a result, be recognised. If 10 or more m.u. of œstrogenic hormone per c.c. of horse's urine are found, the masculine sex may be deduced.

In the urine of the castrated horse (gelding), I discovered only very small quantities of hormone, less than 0.3 per cent of the amount in the urine of the stallion. Similarly the young, sexually immature stallion (colt) excretes only very small quantities of hormone (about 0.2–0.5 per cent). These results appear to me to show that the testes of the horse must be held responsible for the production of the large quantities of hormone. By means of acetone-alcohol extraction I was able to demonstrate the presence of 23,100 m.u. in the two testes of a stallion, together weighing 350 gm. *These values show that the testis of the horse is the richest tissue known containing œstrogenic hormone.* According to my analyses, the hormonic content of both testes of the stallion is more than 500 times as great as that of both ovaries of a sexually mature woman and about 300 times as great as that of both ovaries of a sexually mature mare. The two testes of the horse, together weighing 350 gm., contain four to five times as much hormone as a human or horse's placenta weighing 500 gm. In contradistinction to the testis, the epididymis of the stallion contains no hormone (less than 10 m.u. in an epididymis weighing 5.4 gm.). In the fæces of the stallion I found quantities varying from 1,000 to 10,000 m.u. per kgm. The blood contains less than 800 m.u. per litre.

The mass excretion of œstrogenic hormone in the urine of a male animal is, according to the experiments I have so far carried out, a peculiarity of the equines. Thus, I found for the male zebra, 36,000 m.u., the Gravy zebra, 40,000 m.u., the ass (stallion), 3,300 m.u., and the kiang (Asiatic wild ass), 3,300 m.u. per litre of urine, whereas for the bull and the dromedary (stallion) less than 330 m.u. per litre of urine were found.

Similarly the high hormone content of the testes is to be found only among the Equidæ. In the two testes of a bull, together weighing 420 gm., less than 21 m.u. were found, that is, less than 0.09 per cent compared with horse's testes (horse's testes, 66,000 m.u. per kgm., bull's testes, less than 50 m.u. per kgm.).

It should be pointed out that the male sex hormone — as tested by the comb of a cock—is not excreted in increased quantities in the urine of the stallion. Gonadotropic hormone, prolan, and corpus luteum hormone are not excreted at all.

As is well known, œstrogenic hormone is readily soluble in all organic solvents. If human urine is shaken up with any solvent not miscible with water (ether, benzol), most of the hormone passes into the solvent. On the other hand, as I have already shown[2], the hormone in the urine of the pregnant mare cannot thus be extracted with these solvents. If, however, the urine is first made acid (to congo-red) with mineral acid and boiled for 5 minutes, then the hormone can be extracted with ether or benzol. As regards stallion's urine, I made the following observations:— If the untreated urine be shaken up with ether or benzol, hormone can be extracted, but only from 5 to at most 25 per cent is taken up by the ether. The main quantity of hormone can only be extracted if it is acidified and boiled for several minutes before extraction with ether or benzol. The hormone can be almost completely extracted from testicular tissue simply by treatment with ether or benzol. The alteration in solubility of the hormone described occurs, therefore, in the animal outside the testes.

The œstrogenic hormone which is excreted in the urine of the stallion shows so far exactly the same biological properties as are known in the case of the female sex hormone (follicular hormone, folliculin, œstrin). For example, growth of uterine muscle and proliferation of the uterine mucosa are enormously stimulated by even small quantities of stallion's urine. After five daily injections each of 0 5 c c of stallion's urine, the weight of the uterus of a young rabbit weighing 1200 gm. rose from 0 47 gm to 1 8 gm On introducing larger quantities of urine (twelve daily injections each of 3 c c of stallion's urine) the weight of the uterus rose from 0 47 gm to 5 48 gm and the weight of the vagina from 0 15 gm to 2 48 gm. The uterine musculature showed a great increase in muscle cells (hyperplasia), but especially great was the proliferation or what might be more correctly termed the hyperproliferation of the uterine and vaginal mucous membranes After the injection of stallion's urine there was a retardation of testicular growth in the infantile male rat (antimasculine reaction)

In such chemical properties as have hitherto been observed, the œstrogenic hormone in stallion's urine corresponds with follicular hormone, in which connexion attention is invited to its solubility described above We are now occupied with the exact characterisation of the hormone

The details of the investigations and the importance of the reported findings in relation to the biology of the sex hormones will be discussed in a comprehensive publication

I take this opportunity of expressing my best thanks to Sir Peter Chalmers Mitchell for the gift of material and to Dr Bernard Homa, of London, for the translation

A Source of Error in Photometry

In the course of spectroscopic work in this Institute, a source of error in photographic microphotometry has been discussed, which under certain conditions, especially in the case of band spectra, may be rather serious It is well known that the use of a wide photometer slit causes an error in the determination of the maximum blackening of a spectral line on the plate, the line appearing broader and less intense in the centre than by correct measurement with a narrow slit It is, however, easily overlooked that an error arises also in the integral intensity of the line, and since the matter, so far as we know, has not been dealt with in the photometric literature, it may be of interest to publish some calculations of the error under various conditions

For the sake of simplicity, we will assume that the blackening on the plate and the intensity of light are proportional, so that their integrals are equivalent For the distribution of intensity in the spectral line we choose the Gaussian function $i = i_0 e^{-k^2(\nu-\nu_0)^2}$ (i = intensity, ν = frequency, k = constant). The blackening S is as usual defined by $S = \log J_0/J$.

The curve S in Fig 1 represents the actual blackening on the plate, the curve J in Fig 2 is the photometer curve of the line when using an infinitely narrow slit. Using a slit of the width d means taking the mean J' of the function J in the interval $\nu \pm d/2$. It is easily seen that the integrals of the curves J and J' in Fig 2 are equal, that is, the area a is equal to the sum of the areas b. But when we calculate the blackening S' from the formula $S' = \log J'/J_0$, the area a will have a greater weight than the areas b, so that the area A in Fig. 1 becomes larger than the sum of the areas B. The integral of S' will always be smaller than that of S.

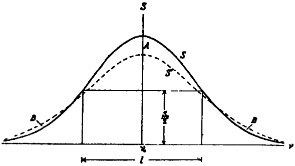

FIG 1

There are two factors which, under the chosen conditions, influence the magnitude of the error, namely, the maximum blackening S_0 and the ratio $p = d/l$ (l is defined in Fig 1) In the table given below, the error $\int_{-\infty}^{+\infty}(S-S')d\nu$ is given as a percentage of $\int_{-\infty}^{+\infty} S\,d\nu$ for different values of S_0 and p Since the mathematical treatment of the problem leads to insoluble integrals, the values of the error have been obtained by a graphical method and are, therefore, not very accurate

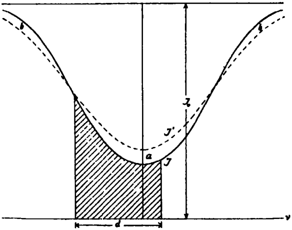

FIG 2

S_0 \ p	0 364	0 455	0 909
0 155	0 24	0 41	1 9
0 398	1 1	1 7	5 2
0 699	1 6	2 5	8·6

The tabulated values of the error may be very roughly taken together in the formula $\Delta = 16 . S_0 p^2$, though Δ is of course in reality a much more complicated function of both S_0 and p.

Radiative Collisions of Neutrons and Protons

IT has recently been shown by Lea[1] that the passage of neutrons through paraffin wax and through liquid hydrogen gives rise to a gamma radiation of $1\text{–}6 \times 10^6$ e. volts energy, as well as recoil protons. As pointed out by Lea and Chadwick, the energy of these rays corresponds roughly to that which would be emitted in the radiative combination of a neutron and a proton to form a diplon We have therefore calculated the probability of such a radiative collision on the assumption that the neutron behaves as a fundamental charge-free particle throughout the collision, so that the radiation arises only from the acceleration of the proton by the field of force of the neutron. A dipole moment may then be associated with the system and the calculation carried out in the usual manner[2] The result is that, for the range of energies involved in the experiments, combination should not take place more frequently than once in every 1000 collisions (the effective radius for diplon formation is about 2×10^{-14} cm). This is much smaller than the observed frequency of about 1 in 4 collisions We have also calculated the probability of a proton radiating in the impact without binding taking place, and find it to be even smaller. These results do not depend appreciably on the form of interaction assumed between neutron and proton

It is of interest to note that if we assume that the neutron is a complex particle consisting of a proton and an electron, and that there are exchange forces between the neutron and proton of the type suggested by Heisenberg[3], then we obtain a much smaller probability of combination (of the order of one effective collision in 10^6), for with this model the dipole moment of the neutron-proton system vanishes[4] In view of the discrepancy between theory and observation, and also in view of the different efficiencies to be expected for the process according as the neutron is or is not a fundamental particle, it is clearly important to obtain additional information about the nature of the neutron-proton collision.

Remarkable Optical Properties of the Alkali Metals

IN a recent communication, Zener[1] has given an interesting interpretation of the peculiar optical properties of the alkali metals discovered by Wood[2], differing from that which I previously suggested in these columns[3]. A closer consideration of the problem has led me to the conviction that the viewpoint of Zener, although not fully accounting for all the observed facts in its original form, can serve as a suitable basis for the discussion of the phenomena in question if modified in the following way .

Zener starts from the assumption that the conduction electrons of the alkali metals are practically free. In the absence of temperature agitation of the lattice, they will then have only the one sharp resonance frequency, $\nu = 0$, and no resonance frequencies corresponding to quantum jumps from the occupied to the unoccupied stationary states. As stated by Zener, the dielectric constant of the metal at frequency ν is in this case given by

$$\varepsilon = 1 - \frac{Ne^2}{\pi m \nu^2},$$

where N is the number of conduction electrons per unit volume, e the electronic charge and m the electronic mass. The electrical conductivity σ, giving the current in phase with the electric vector of the radiation, on the other hand, is zero for all frequencies except for $\nu = 0$, where it becomes infinite The metal will hence be totally reflecting, even at perpendicular incidence, for all frequencies for which $\varepsilon < 0$, that is, below the frequency ν_0 given by

$$\nu_0^2 = \frac{Ne^2}{\pi m}. \qquad (1)$$

Zener tries to account for the results of Wood, according to whom the transparency of thin films of the alkali metals, in going towards shorter wave-lengths, becomes greater by a factor of the order 100,000 within a rather narrow frequency interval in the ultra-violet, by means of this phenomenon of total reflection, finding from (1) values of ν_0 which agree rather well with Wood's experimental data. The difficulty with this interpretation is that actually the alkali metals are by no means totally reflecting in the visible region, the coefficient of reflection in the case of potassium[4], for which the high transparency begins at about 3000 A., decreasing from about 90 per cent at 5000 A to about 10 per cent at 2500 A Wood's results must therefore with certainty be ascribed to a change in the coefficient of extinction rather than to a change in the reflecting power.

Now such a change in the extinction coefficient can be obtained on the same fundamental assumptions as introduced by Zener, if it be remembered that the resonance frequency $\nu = 0$ is not infinitely sharp but suffers a broadening due to the impacts of the conduction electrons with the metallic lattice, which the temperature agitation of the latter brings about. Specialising formulæ which I have given elsewhere[5] for the case of free electrons, the half breadth δ of the resonance line $\nu = 0$ is found to be

$$\delta = \frac{Ne^2}{2\pi m \sigma_0}, \qquad (2)$$

where σ_0 is the electrical conductivity for constant fields, while σ and ε are given by

$$\sigma = \frac{\sigma_0 \delta^2}{\nu^2 + \delta^2}, \quad \varepsilon = 1 - \frac{2\sigma_0 \delta}{\nu^2 + \delta^2}.$$

The index of refraction n and the coefficient of extinction $\varkappa$ are found from σ and ε by means of the relations[6]

$$n^2 = \tfrac{1}{2}\left(\sqrt{\varepsilon^2 + 4\sigma^2/\nu^2} + \varepsilon\right),$$
$$\varkappa^2 = \tfrac{1}{2}\left(\sqrt{\varepsilon^2 + 4\sigma^2/\nu^2} - \varepsilon\right).$$

In the table at the end of this letter I have computed the values of σ, ε, n and $\varkappa$ for potassium in the interesting region of wave-lengths, using $\sigma_0 = 1{\cdot}35 \times 10^{17}$, which leads to $\delta = 4{\cdot}11 \times 10^{12}$ according to (2). As may readily be seen, there exists a critical frequency below which n is abnormally small, while above it $\varkappa$ practically vanishes , the critical frequency with great approximation is equal to ν_0 as given by (1).

The vanishing of $\varkappa$ above ν_0 explains Wood's results Below ν_0, the values of n and $\varkappa$ may be compared with a few direct experimental determinations In the case of potassium[7], for wave-lengths 6650 A, 5890 A, 4720 A, n has the values 0 066, 0 068, 0 070, $\varkappa$ the values 1 77, 1 50, 1 00 The values of $\varkappa$ agree fairly well with the computed values, the values of n are indeed exceptionally small but still larger than the computed values by a factor 10. The discrepancies must evidently be ascribed to the fact that the electrons are not completely free as assumed If the electronic transitions, made possible by the binding, cause σ to be about 10 times as large as in the accompanying table, values of n agreeing more closely with experiment will be obtained, while the general behaviour of n and $\varkappa$ discussed above is not obliterated as in the case of other metals having a σ about 1000 times as large (for example, silver[8])

$\nu \times 10^{14}$	λ (A)	σ 10^{14}	ϵ	n	$\varkappa$
4	7500	14 3	− 5 94	0 0147	2 44
5	6000	9 13	− 3 43	0 0099	1 85
6	5000	6 34	− 2 08	0 0074	1 44

Diffusion of Water in a Zeolite Crystal

IT has long been known that minerals of the zeolite family show remarkable properties which indicate that certain constituents of the crystal lattice are movable The exchangeability of cations and the possibility of driving out the water of constitution and substituting it with other substances in a reversible way without spoiling the crystal can be understood only by such an assumption X ray structure determinations have shown that zeolite lattices contain wide meshes, through which a migration of matter may very well be assumed to take place[1]

I have made an attempt to study this migration quantitatively For this purpose I have chosen an optical method, which makes a direct observation of the migration possible The reversible dehydration and the substitution of the water of constitution with other substances bring about characteristic changes in the optical properties of the zeolites. The refractive index, the extinction angle, and the double refraction may change considerably

When studying the rehydration in moist air of partially dehydrated crystals of heulandite between crossed nicols in the polarising microscope, Rinne, Gaubert[2,3] and others have observed a diffuse black band, parallel to the surface, slowly migrating from the surfaces towards the interior of the crystal. The position of the black band is dependent upon the angle between the crossed nicols and the crystal axes For any value of this angle, those parts of the crystal that have a water content corresponding to this extinction angle will appear black No quantitative study of the phenomenon has, however, been made so far

I have been able to confirm these observations When using monochromatic light and strongly dehydrated crystals, I have observed as many as seven bands, the number depending upon the degree of dehydration, the thickness of the crystal, and the wave length of the light These bands (except that nearest the edge, which evidently is identical with the above mentioned extinction angle band) do not move when the nicols are turned and are evidently due to the change in double refraction known to accompany the dehydration Each band corresponds to a water content with a double refraction giving a phase difference of $n\lambda$. If we know the exact relation between water content and extinction angle or double refraction, a very detailed analysis of the distribution of water in the crystal after different times of diffusion can be made, for example, by measuring the position of all the bands with an ocular screw micrometer The extinction angle band can be used only for the highest water content, since the angle is independent of the change in water content, except for the last few per cent entering the crystal. In all other cases the double refraction bands have to be used

Of course all quantitative measurements must be made in a vacuum Heulandite crystals, carefully selected to secure material as optically homogeneous and free from cracks as possible, were ground to thin plates parallel to the cleavage plane Such a crysta was placed in a specially constructed vacuum microcuvette, which could be connected to an evacuated container with air-free water, kept at constant temperature in a thermostat The cuvette could be heated

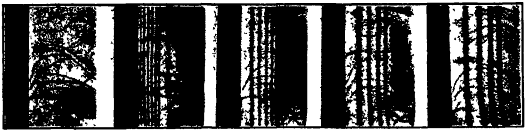

FIG 1

to any desired temperature with a small, closely fitting electric oven. The temperature of the crystal was measured with a thermocouple

Sorption isobars of water in heulandite at different pressures and temperatures were determined with a sorption balance apparatus to be described elsewhere By varying the temperature of the crystal and the water vapour pressure in the cuvette, the crystal could thus be given any accurately known water content, and the corresponding changes in the optical properties could be determined

Diffusion experiments were made in this apparatus with crystals dehydrated by different amounts When the crystal had attained equilibrium, the stopcock to the water container was opened, and water vapour of a constant, accurately known pressure was let in Observations were made in monochromatic light from a Pirani sodium lamp. *Fig* 1 shows a series of photomicrographs from such an experiment

The measurements show that the displacement of each band is proportional to the square root of time, in agreement with the requirements of the general diffusion equation $\delta c/\delta t = \delta/\delta x\ (D\frac{\delta c}{\delta x})$ (Boltzmann[4]) Calculation of the diffusion constant *D* from the observations on each band shows that there is a strong drift of *D* with the concentration At 20° C in a direction normal to the face *t* (Des Cloiseaux notations), the constant varies from $3\ 2 \times 10^{-7}$ to $8\ 9 \times 10^{-7}$ cm ^{2} sec $^{-1}$, while the concentration increases from 12 0 to 17 5 per cent. The diffusion shows a strong anisotropy, being immeasurably small normal to the cleavage plane and showing in this plane a minimum value normal to the face c (Fig 2) The ratio between the maximum and minimum values in this plane corresponding to the 'diffusion ellipse' is 12 5

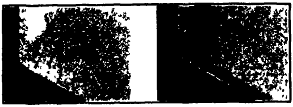

FIG 2

It is planned to study the diffusion of other gases, and also to use other zeolites, in the first place some of those for which complete X-ray structure determinations have been made. Investigations of this kind bear some relationship on the well-known surface diffusion studies[5,6]. In both cases the diffusing molecules meet vacant lattice points in their path

A detailed report of the investigation and a discussion of the results will appear shortly.

Weiss Constant of Paramagnetic Ions in the *S*-State

THE influence of crystalline and molecular fields on the magnetic behaviour of paramagnetic ions has formed the subject matter of several theoretical papers by Bethe, Van Vleck and others[1]. In the case of ions in the *S*-state (for example, Mn++), the susceptibilities of which are due wholly to the *spin* moments of their electrons, the theory leads to the following result the Weiss constant θ, appearing in the well-known relation $\chi = C/(T-\theta)$, is zero; that is, the susceptibilities of these ions conform to the simple Curie law of inverse dependence on absolute temperature This result has been fully verified experimentally by Jackson[2] and others in the case of manganous salts *in the solid state* But, for these salts *in aqueous solution*, in which state one would, *a fortiori*, *expect this result to hold true*, the experimental data at present available[3] do not follow this rule, they yield large values for θ, namely, 24-28 for the ion in $MnCl_2$, and 22-27 for the ion in $Mn(NO_3)_2$

I have therefore made some extensive measurements with aqueous solutions of these salts, of various concentrations, from room temperature to about 98° C In all cases I find that the susceptibility of the Mn++ ion obeys the simple Curie law, the maximum value of θ obtained in these measurements was less than 3

The Curie constant, *C*, of the Mn++ ion, obtained in these measurements, was 4 19 per gm ion in $MnCl_2$ solutions, and 4 11 per gm ion in $Mn(NO_3)_2$ solutions These correspond to 28 8 and 28 5 Weiss magnetons respectively, as against previous values of 28 1 for solution and 29 0 for solid

A detailed report of this work, which was carried out under the guidance of Prof K S Krishnan, will be published in the *Indian Journal of Physics*

Photo-Oxidation of Nitrite to Nitrate

THERE is considerable difference of opinion regarding the possibility of the oxidation of nitrites by oxygen to nitrates Berzelius reported that when aqueous solutions of alkali nitrites are boiled in air, they absorb oxygen with the formation of nitrates. G Lunge and E Frémy, J. Lang[1] and others showed that aqueous solutions of nitrites pass into nitrates. According to R. Abegg and H Pick[2], oxygen of the air oxidises a solution of silver nitrite to silver nitrate. On the other hand, E Divers[3], Sir P C. Rây[4], C Russworm[5], M Oswald[6], and others observed no oxidation of solutions of nitrites in air C Matignon and G Marchal[7] reported that an aqueous solution of sodium nitrite is not oxidised by prolonged contact with oxygen, under a pressure of 50-55 atmospheres, even in the presence of a catalyst But when the pressure is raised to 175 atmospheres and temperature to 395°-530°, solid sodium nitrite is almost completely oxidised to nitrate.

The formation of nitrates from nitrites in acidic solution is easily explained from the point of view that the solution of nitrous acid undergoes the following change

$$3\,HNO_2 \rightleftarrows HNO_3 + 2NO + H_2O.$$

In presence of air, the nitrous acid may be completely converted into nitric acid This seems to be the explanation of the observation of A. Muntz[1] regarding the conversion of nitrites to nitrates in soil, in presence of carbonic acid and air Dhar[2] and collaborators have shown that solutions of sodium nitrite can be appreciably oxidised to sodium nitrate by passing air in presence of inductors like ferrous hydroxide, sodium sulphite, etc , and the amount of oxidation increases with the increasing concentrations of the inductor and the nitrite solution and with the time for which air is passed W P Jorissen and C van den Pol[10] and W Reinders and S I Vles[11] could not detect any oxidation of sodium nitrite by oxygen in presence of sodium sulphite because they did not take sufficient sodium sulphite and the contact with oxygen was not long enough

Recently we have observed that dilute solutions of sodium nitrite or potassium nitrite, when exposed to sunlight and air, are oxidised to nitrate The velocity of the photochemical oxidation is greatly accelerated by the presence of titanium, zinc and iron oxides (TiO_2, ZnO and Fe_2O_3) Titanium oxide seems to be the best photosensitiser. The following are some of the results obtained by us

Concentration of nitrite	Volume exposed	Time of exposure	Catalyst	Per cent nitrite unchanged	Amount of nitrogen obtained after exposure
		Sodium Nitrite			
N/525	100 c c ≡ 0 00132 gm nitrogen	100 hours	5 gm TiO_2	0	0 00126
,,	,,	,,	5 gm Fe_2O_3	0	0 00126
		Potassium Nitrite			
N/112 4	100 c c ≡ 0 00620 gm nitrogen	100 hours	5 gm Fe_2O_3	0	0 00618

Warburg[12] and Villars[13] studied the photodecomposition of solutions of potassium nitrate in ultra-violet light Dhar and Sanyal[14] observed the slow decomposition of nitrates in sunlight The photodecomposition of potassium nitrate is a slow reaction and has a low quantum yield in ultra-violet light and tropical sunlight It seems, therefore, that in presence of light, the following equilibrium is obtained .

$$2KNO_3 \rightleftarrows 2KNO_2 + O_2$$

It appears that in dilute solutions and in presence of an excess of oxygen, practically the whole of the nitrite is oxidised to nitrate in light From the foregoing observations it seems clear why discordant results regarding the oxidation of nitrites to nitrates by different workers were obtained. Experiments done in laboratories having more diffused light probably resulted in greater oxidation of the nitrite.

In publications from this Laboratory[15], it has been shown that amino acids can be readily oxidised to ammonia in presence of air and light. Also, ammonia and its salts are oxidised to nitrites in presence of surfaces like titanium and zinc oxides, sterilised soil, etc , in the complete absence of bacteria, when exposed to air and sunlight. We have now observed that nitrites can also be oxidised photochemically to nitrates in the absence of bacteria It appears, therefore, that the important processes of ammonification, nitrification and the conversion of nitrite to nitrate taking place in soil, which have been ascribed so far solely to bacterial activity, can be induced in presence of sunlight Hence we are of the opinion that these processes can be photochemical rather than bacterial, specially in tropical countries where the number of bacteria is small, being mostly killed by the high temperature of the soil during the summer months

Anisotropy of Spherical Sound Waves

THE amplitude of vibrations on the wave surface of a spherical light wave may, or may not, be homogeneous. According to the classical electromagnetic theory of light, for a spherical wave emitted by a linear oscillator, the intensity is at a maximum in the direction perpendicular to the axis of the oscillator, and at a minimum in the direction of prolongation of the axis.

It is interesting to find experimentally whether the distribution of intensity of a spherical sound wave is homogeneous or presents any analogous anisotropy

To test this, the intensity of sound emitted during spark discharges is measured by means of a Rayleigh disc suspended in the stream of the sound wave. The discharge is produced in a circuit which consists of an alternating current transformer with four Leyden jars joined in parallel with a spark gap, which is formed by two thin steel rods placed at several millimetres distance along a straight line The steel rods are 2 mm in diameter This small size was adopted in order to diminish any possible disturbance due to massive solid obstacles placed in the path of the sound wave. The transformer is used instead of an induction coil, because the latter needs a mechanical interrupter which produces undesirable noises when it is working. The spark gap is mounted on a rotating table provided with a scale, such that the gap can rotate around its centre and its orientation can be determined accurately from the scale

Observations were made of the deflections of the disc for different orientations of the spark. The deflections were proportional to the intensity of the incident sound wave. Hence the relative intensities around a great circle on the spherical wave surface can be determined Special attention was paid to making the discharge as uniform and constant as possible. A large number of observations was carried out. Some typical results when the gap is 6 mm.

in length and the disc is placed at a distance of 68 cm. from the spark are given below.

θ	0	90	180	270	360
d	0 803	1 09	0 80	1 07	0 81
I	1 00	1 36	1 00	1 33	1 01

θ = the angle between the direction of observation and the direction of the spark
d = the deflection of the Rayleigh disc
I = the relative intensity of sound

These results show definitely that the intensity of spherical sound waves emitted by a spark is distributed anisotropically on the wave surface: the intensity is a maximum in the direction perpendicular to the direction of the spark and a minimum in the direction of prolongation of the spark

The experiments are being continued with different methods of measuring the intensity of sound, and a more detailed report will appear shortly

Crystal Structure of Copper Sulphate

We have been able to determine the structure of copper sulphate pentahydrate, which was the first crystal used by Friedrich and Knipping to diffract X-rays The unit cell has dimensions ·

$$a_0 = 6\ 12\ \text{A.},\ b_0 = 10\ 7\ \text{A},\ c_0 = 5\ 97\ \text{A},$$
$$\alpha = 82°\ 16',\ \beta = 107°\ 26',\ \gamma = 102°\ 40,$$

and contains two molecules of $CuSO_4\ 5H_2O$ The only symmetry possessed by the crystal is a centre of inversion

The copper atoms lie on the centres of symmetry at (0 0 0) and ($\frac{1}{2}$ $\frac{1}{2}$ 0) and the sulphur atoms on the general position (0 01, 0 29, 0 64) Each copper atom is surrounded by an octahedron consisting of four water molecules and two oxygen atoms, suggesting that there are direct bonds from copper to oxygen. This differs from structures like $BeSO_4\ 4H_2O$ and $NiSO_4\ 6H_2O$, in which the bonds joining the groups are between water and oxygen[1]. That the two octahedra are not equivalent is the explanation of the dehydration to $CuSO_4\ 3H_2O$ and then to $CuSO_4\ 1H_2O$.

The odd water molecule touches two oxygens of different SO_4 groups and two waters of different octahedra, and would seem to play an important part in holding the structure together The structure satisfies all the generally accepted requirements of inter-atomic distances.

The copper and sulphur positions were obtained from rotation photographs of copper sulphate and copper selenate crystals, and the oxygen and water positions from a double Fourier synthesis projecting on to (001)

We have to thank Prof. W. L. Bragg for allowing us to make the necessary measurements with the X-ray spectrometer at Manchester. We hope to publish further details elsewhere.

The so-called Terminal Parenchyma Cells in the Wood of *Terminalia tomentosa*, W. and A.

In the literature dealing with European and American timbers, frequent mention has been made of the presence of terminal parenchyma cells in the wood of *Fraxinus excelsior*[1], *Populus* sp [2], *Betula lutea*[3] and *Acer sachharum*[3]. There can be no doubt about the validity of these statements, for they were based on intensive study of those timbers both in the field and in the laboratory

While dealing with Indian timbers, Brown[4] has mentioned the presence of terminal parenchyma cells in the wood of *Terminalia tomentosa*, W and A I have done the same on one occasion[5]. But none of these statements was based on the results of studying wood taken out periodically from a living tree and actually finding out whether these parenchyma cells were terminal or not From the examination of the timber of this species in the laboratory, some of the parenchyma cells appeared to be distributed in the same way as the terminal parenchyma cells in the wood of *Fraxinus excelsior, Betula lutea*, etc, and they were, therefore, described as terminal.

During the last three years, however, while studying the formation of growth rings in the wood of *Terminalia tomentosa*, W and A, I have found that the so-called terminal parenchyma cells are not really formed as the last tissue of the annual ring, but are the first type of cells formed at the beginning of the growth season So, instead of being terminal, they are actually initial

So far as my information goes, no textbook has mentioned this type of parenchyma distribution in any wood Details of this investigation will soon be published. Meanwhile, it would be interesting to know whether anyone else has noticed this type of parenchyma cell distribution in any wood.

White Cats and Deafness

Mrs Bamber's recent article in the *Journal of Genetics*[1] on the correlation between white coat colour, blue eyes and deafness in cats is of importance and interest It may perhaps be supplemented by a brief note on the same subject

Mrs. Bamber states: "It has long been recognised that blue-eyed white cats are often deaf, whereas white cats with yellow or greenish eyes have normal hearing." She records the existence of a white, blue-eyed male cat which is not deaf. Another case is that of a cat with one blue and one yellow eye, which is "completely deaf on both sides."

I have at present a male, polydactylous, white cat with yellow eyes, which is completely deaf on both sides. This animal completes the possible combination of eye colour, deafness and normal hearing. As yet this animal is too young to breed. It is hoped, however, that he may, in the near future, be tested genetically

In the meantime the correlation between blue eyes and deafness is certainly not a perfect one If the two characters are due to a similar physiological or genetic agent, it seems certain that its effects are sufficiently variable to enable them to operate in either the eyes or the ears, to the exclusion of the other location

Spawning Date of the Common Frog

IN a former communication[1] I announced certain conclusions on the effect of the weather upon the spawning date of the common frog, *Rana temporaria* Since then, a number of new facts have come to light

Although wet days and spawn days are not associated, rainfall affects the date of spawning The effect, parallel to the temperature effect previously reported, is due mainly to the total rainfall of the month prior to spawning.

These conclusions are confirmed by the relation which exists between the altitude of a pond and its spawn date In south-west England, spawning is, on the average, earlier the higher the pond observed In the Midlands and in south-east England, the same is true but the effect is much less This distribution, both altitudinal and geographical, is the same as that of orographical rainfall.

The view that the weather is acting directly on the frogs themselves conflicts with my observations on migration Although frogs hibernate in a variety of situations, they arrive at a particular breeding pond from different directions simultaneously, although this pond may differ considerably in its spawn date from another close by There is, moreover, a difficulty in accepting a long period rainfall effect acting directly on frogs hibernating under water The pond seems to be the unit for both spawning and migration, probably two aspects of one problem

The observations suggest that spawning is dependent on pond periodicity It is known that the periodicity of pond plants is affected by temperature and especially rainfall, which acts by the washing of phosphates from the soil into the pond[2] Atkins, in the paper cited, found that ponds with streams running into them developed their algal maxima earlier than the others, due to the increased phosphate supplies, and I found, from the results of a postal questionnaire, that ponds without streams tended to be without frogs

The link between algal (or other plant) periodicity and spawning is being sought in the production of odour by the water plants The smell of standing water is a problem of water-works technology, with a large literature, which has received little attention from workers on the migration of terrestrial animals breeding in the water. The odours are, in general, not those of decay, but are due to essential oils secreted by the water plants, plankton, etc, and are markedly periodic in their occurrence.

An endeavour was made last season to see whether plankton was responsible by asking a number of observers to send me samples of the water of their ponds, from which I concluded that planktonic organisms are not concerned. An attempt is being made this spring to correlate phosphate changes in the water with spawning.

The form of the generalised curve showing the progressive changes in the number of ponds in an area having spawn is deducible from some simple assumptions on the mechanism, and the reasoning shows that the date on which the maximum number of ponds develop the postulated effect will not be coincident with the date on which the maximum number of spawn reports occur, but will be later

A detailed account will be published later.

I wish to thank those phenological observers who took so much trouble in the postal scheme, and the Royal Meteorological Society for data courteously supplied.

A Recent Sedimentary Volcanic Tuff

ON November 3, 1931, during a trawling survey of Falkland Island waters, the R R S *William Scoresby* made a haul with a commercial trawl in 98 m of water on a position 45° 56′ S., 66° 24′ W. situated in the Gulf of San Jorge, off the Patagonian coast

The contents of the trawl consisted mainly of several bushels of slabs, 5–10 cm. thick, of a compact clay-like rock. Its colour was greenish-grey changing to olive-buff when dry Under the microscope, the rock is seen to consist of some very finely divided 'clay' substance, too finely divided to be identified by means of the polarising microscope, but a much more abundant constituent is colourless volcanic glass in flakes varying in size from 0·15 mm downwards With this are birefringent grains of feldspar (varying in size from 0 06 mm in diameter downwards) and a very few green grains resembling glauconite The colourless glass and the feldspar are similar to the material which forms the dust clouds emitted by volcanic eruptions in the Andes and has on occasions travelled the whole breadth of the Argentine Republic In dust collected at Buenos Aires after the eruptions in the Andes in 1932, the particles ranged from 0 2 mm downwards for the colourless glass, and from 0 1 mm. downwards for the chips of feldspar and other minerals. There seems no doubt that the rock has been formed by the deposition in the sea of volcanic dust windborne from the Andes. If so, it is an excellent example of the mode of deposition of some of those sedimentary volcanic tuffs which have long been known among deposits of volcanic origin.

The associated fauna was very meagre, consisting almost entirely of an alcyonarian of the genus *Renilla* together with a few polychætes

Quaternary Intermetallic Compounds

INVESTIGATORS of metallic systems by thermal and X-ray methods have found many binary intermetallic compounds; they have found, however, only a few ternary and no quaternary compounds. If a metal or metals of one class (zinc, tin, cadmium, mercury) reacts in mercury at ordinary temperature with one of another (copper, iron, cobalt, nickel, manganese), many binary and ternary compounds result[1].

Recently we have succeeded in getting three of the first class to unite with copper to form reasonably stable quaternary compounds, the analysis of which by the volumetric processes of the laboratory presented no difficulty Seven of them were obtained by the reaction between zinc and the simplest ternary compound which forms in mercury, namely, $SnCu_3Hg_7$ Their approximate empirical formulæ are $Sn_4Cu_{12}Zn_4Hg_8$, $Sn_5Cu_{15}Zn_5Hg_9$, $SnCu_3ZnHg_8$, $SnCu_3ZnHg_6$, $Sn_4Cu_{12}Zn_4Hg_{48}$, $Sn_4Cu_{12}Zn_7Hg_{21}$ and $Sn_4Cu_{12}Zn_7Hg_{33}$ Four others have been prepared by the reaction between tin and the simplest binary compound which forms in mercury, namely, ZnCu Their approximate empirical formulæ are $Zn_3Cu_3SnHg_7$, $Zn_6Cu_6SnHg_9$, $Zn_{40}Cu_{40}Sn_5Hg_{14}$ and $Zn_{40}Cu_{40}Sn_{12}Hg_{31}$ Cadmium forms ternaries with copper and mercury without difficulty but not with copper and zinc or with copper and tin. Quaternaries or quinaries including cadmium cannot, in consequence, be so prepared.

Ternary and quaternary compounds formed in mercury, so far as the work has gone, may be regarded as derived from known compounds of mercury and copper in which other metals of the *B* sub-group of the Periodic Classification partly replace the mercury, an atom of the quadrivalent tin counting as two divalent atoms of mercury, zinc, cadmium and mercury being equivalent Thus $SnCu_3Hg_7$, $SnCu_3ZnHg_6$ and $Sn_4Cu_{12}Zn_7Hg_{21}$ may be regarded as derived from $CuHg_3$, a compound which has been prepared in mercury but otherwise is unknown in metallurgy. (The corresponding $CuZn_3$, however, is well known) Similarly, $Sn_5Cu_{15}Zn_5Hg_9$, $Zn_{40}Cu_{40}Sn_5Hg_{14}$, and the ternaries (not mentioned above) $Zn_2Cu_5Hg_6$ and $Zn_4Cu_5Hg_4$, may be regarded as derivatives of Hg_8Cu_5, which has been prepared in mercury. (The corresponding Zn_8Cu_5 and Cd_8Cu_5 are well known in metallurgy)

If this process of derivation is legitimate, our work is brought into line with that done by thermal and X-ray methods. In addition to the binary compounds which form easily in mercury or by other methods, there is the possibility of a large number which do not Their existence, possible and actual, has enabled us to confirm and extend considerably the rules connecting the numbers of valency electrons and atoms which were put forward first by W Hume-Rothery[2], namely, for compounds between such metals as tin, zinc or cadmium and metals like copper, silver or iron, there are characteristic ratios of valency electrons to atoms of 3 : 2, or 21 · 13 or 7 · 4, that is to say, for 21 electrons there may be 14, 13 or 12 atoms in the compound. We find for a given number of electrons there are ranges of atoms. For copper united with a divalent metal of the *B* sub-group there may be for 42 electrons 21, 22, 23, 24, 25, 26, 27 or 28 atoms; for 18 electrons 12, 13, 14, 15 or 16 atoms. In tin-copper compounds, for 42 electrons there may be 14, 15, 16, 17 or 18 atoms, for 28 electrons, 12, 13, 14, 15 or 16 atoms and for 21 electrons, 12, 13 or 14 atoms It would thus appear that the total number of valency electrons—18, 21, 28 or their multiples—is even more characteristic of an intermetallic compound than the ratio of electrons to atoms

In reckoning valency electrons, metallurgists count copper and silver as having each one electron, zinc, cadmium and mercury as having each two electrons, and lead and tin as having each four. To fit transition metals like iron, cobalt and nickel into the schemes, they regard their atoms as contributing no valency electrons to the compound Our results show, however, that in certain compounds (mainly when these metals are in excess) iron, cobalt, nickel, manganese, and possibly other transition and pre-transition metals of the Periodic Classification, may be regarded as having each one electron, in other compounds (mainly when the *B* metal is in excess) the transition metal acts as if it had no electron Thus, in $SnFe_3$, iron acts as if it had one valency electron; in $Zn_{21}Ni_5$, nickel acts as if it had no valency electron.

Passage of Hydrogen through Steel

INVESTIGATIONS have recently been carried out by Dr J M. Bryan and myself at the Low Temperature Research Station, Cambridge, on the relative rates of corrosion by dilute solutions of citric acid of different samples of mild steel sheets such as are used in the manufacture of tin-plate In these tests an attempt was made to eliminate edge-corrosion by making the steel sheet the bottom of the corrosion chamber. This was done by cutting off the bottoms of glass bottles, grinding the edges and coating them with pure vaseline to prevent leakages, and applying the sheet The whole was clamped up tightly in a suitable frame, the sheet itself being in contact on its outer side with a pad of filter paper resting on a wooden block The chamber thus formed was connected to a gas burette so that the hydrogen formed through the action of the dilute acid could be measured, and the whole apparatus was held at 25° C

It was found after a given period that the loss in weight of the sheet indicated that the hydrogen-equivalent of the steel dissolved was far in excess of the hydrogen actually collected This excess was greater than could be accounted for through solution of the hydrogen in the corroding medium, and it appeared therefore that the hydrogen was either absorbed by the metal in considerable qualities or else passed through it and was evolved freely on the outer side. That the latter was more probable was supported by the fact that blisters appeared on the outer side of some of the specimens, showing that the gas passed, at any rate, nearly through the metal and could exert considerable pressures inside it.

A further experiment was therefore carried out in which the metal sheet was clamped so as to form a diaphragm between two flanged hemispherical glass vessels each of which was connected to a gas burette by means of an outlet tube The upper vessel contained the corroding medium which was in contact with the metal and the lower one contained air The air in the headspace of the upper chamber and in the solution was replaced by nitrogen and the whole apparatus was set up in a room held at 25° C

Both the upper and lower burettes soon began to register an increase in volume That in the upper one was the more rapid at first, but slackened later, and when the apparatus was taken down after two days, there was about 30 c c of hydrogen on either side, leaving about 9 c c (calculated from the loss in weight of the sheet) to be accounted for by absorption into the metal and by solution in the citric acid I should be glad to know whether the passage of hydrogen through steel under similar conditions to the above has been recorded

Interaction of Radio Waves

THE phenomenon recently reported by Tellegen[1] whereby the new broadcasting station at Luxembourg appears to interact with that portion of the carrier wave of the Beromunster station which is received in Holland, can be explained by taking into account the effect of such a powerful station (200 kw and $\lambda = 1190$ m) on the mean velocity of agitation (u) of the electrons in the ionosphere Any change in u will produce a change in ν, the frequency of collision of an electron with molecules, and hence a change in the absorbing power of that part of the ionosphere in the vicinity of the station Since this change depends on the magnitude of the electric vector in the disturbing wave, it follows that the absorbing power of this part of the ionosphere will vary in accordance with the modulation frequency of the station, and so the modulation will be impressed in part on any other carrier wave which may traverse this region

We have examined these points quantitatively with the help of data obtained by Townsend and Tizard[2] on the motions of electrons in air, and have arrived at the following conclusions

The amount of modulation of a carrier wave produced by a disturbing station of power P and modulation frequency f is approximately proportional to P and inversely proportional to f There is thus introduced a distortion of the original modulation, at the expense of the higher frequencies of modulation

The variation of the impressed modulation with the wave length of the disturbing station is more complicated, being roughly proportional to $1/\{\nu^2+(p-\omega)^2\}$ where $p = 2\pi c/\lambda$, $\omega = H_p e/cm$ and H_p is the component of the earth's magnetic field perpendicular to the electric vector of the disturbing wave It is clear that the quasi-resonant state ($p = \omega$) can exist only in very localised regions of the ionosphere, and will contribute little to the total impressed modulation, which may be received over the whole path of the wave in the absorbing regions of the ionosphere The disturbance will therefore be greatest when ω is small, that is, when the entire electric vector of the wave lies in the direction of the earth's magnetic field The magneto-ionic theory shows that under European conditions this can occur only for that part of the wave's path which is roughly horizontal In such circumstances ω will always be small for waves much longer than 214 m

We have examined the magnitude of the disturbance which would be experienced at Eindhoven when listening to the Beromunster station, and find that it would become appreciable for values of air pressure in the absorbing regions near those generally accepted The disturbance experienced is proportional to ν^2, so that we should expect increased disturbance at times when the sky wave is weakened by increased absorption, for example, around sunrise and sunset, and in the daytime if signals be audible

It is to be anticipated that the Warsaw station will also exhibit the effect in just appreciable intensity if careful investigation be made It is not to be expected, however, that the very long wave high-power telegraph stations, such as Rugby or Nauen, could produce the effect, for such long wave-lengths are probably reflected at a level in the ionosphere below that which absorbs waves of broadcasting frequencies Neither would such a station appreciably influence the reception of other very long wave stations, since most of the received signal on these wave-lengths is due to the ground wave

The details of our investigation will be published elsewhere in the near future, together with a discussion of the possibility of utilising the phenomenon to derive further information about the ionosphere

Audibility of Auroras and Low Auroras

I WAS much interested in the article "Audibility of Aurora and Low Aurora" by F T Davies and B W Currie which appeared in NATURE of December 2, because I once witnessed an aurora and heard the swishing sounds referred to

During the winter of 1908–1909, while attending Trinity College at Hartford, Conn , I observed a magnificent aurora The light effects gave me the impression that the atmosphere was filled with fog, and that someone was illuminating it by playing a searchlight back and forth The effect was very striking because the display was so close to the ground that I seemed to walk right through the illuminated fog

The sound which I heard is exactly described by the word swishing I do not believe I could say the swishing sound was in unison with the flickering of the lights because the sight was so new and strange that I did not observe it from the point of view of a scientist. All that I can say is the swishing sounds were heard while the lights were changing.

Clay Heads from Ashanti. Capt. R. P. Wild describes and figures in *Man* for January two heads of baked clay from Fomena, Ashanti, which were obtained by Mr. E. A. Burner, of the Political Service, from Nana Kobina Fori, the Omanheno of Adansi, whose capital town is Fomena. Kobina Fori, whose age is estimated at somewhere in the neighbourhood of eighty years, states that although these heads are not now made, he remembers them being made by an old woman when he was a boy. According to his evidence, they were placed on the graves of chiefs, elders, councillors and queen mothers, that is, the most prominent members of the Adansi tribe. At certain times offerings were made to the spirits which were supposed to have taken up their abode in the heads. For this purpose a baked clay ladle was required. The heads are well fired and are made of a fairly fine clay. They are hollow and almost life size. From the absence of the beard and the smaller head it is probable that one of the two heads represents a woman. The features of both heads are rather refined in comparison with the usual cast of countenance in the Ashanti race. This supports the statement that they are meant to represent chiefs, elders, etc., as the ruling classes of the Ashanti show distinct signs of refinement. The side view shows the typical long face of the Ashanti, but with an unnatural flattening of the back from the nape of the neck upward, giving an almost vertical profile. This may be due to artistic license. The conventional representation of the hair is interesting, it being rendered by whorls, cylinders and hollow balls. Kobina Fori stated that human hair (perhaps the hair of the deceased) was inserted in the holes in the cylinders and balls. The faces had been coated with red clay after firing, red being the mourning colour of the Ashanti. Facial markings, it is suggested, may be intended to counterfeit the cicatrices of an Akim slave as a disguise against evil spirits.

Cancer Mortality in the Australian Commonwealth. Deaths from cancer in the Commonwealth of Australia for 1931 per 100,000 of mean population were for males 105, females 97, persons 101 (Dr. M. J. Holmes, *J. Cancer Res. Com. Univ. Sydney*, 5, No. 3, 168; 1933). These rates show a considerable increase on those of the previous year and affected all States except Western Australia. The age-grouping of the population has, however, been altering since 1921, and the proportion of the population in the age-groups 45–64 and over 65 years is now larger than in a standard population, that is to say, a larger proportion of the population reach the 'cancer age' than formerly. Correcting for this, an actual diminution in the cancer mortality in the age-groups below 65 years has become evident in recent years, the rate for 1931 being lower than that for 1921 and for 1911. This diminution may justly be attributed, at least in part, to the efficacy of modern treatment. The mortality rate for sarcoma remains at about the same figure that it was twenty-five years ago.

Golgi Apparatus in Protozoa. Joyce C. Hill (*J. Roy. Micr. Soc.*, 53, Part 3, 1933) states that the Golgi apparatus in the Sporozoa agrees with that in the Metazoa in its reactions to osmic acid and resembles it in general structure and in juxta-nuclear position. During division, the Golgi elements are drawn to each nucleus in approximately equal numbers as in dictyokinesis in Metazoa. There appears therefore to be a true Golgi apparatus in the Sporozoa but there is no such certainty for the other groups. In Amœba, Brown describes globules with clear centres and dark rims which impregnate with osmic acid and may represent the Golgi apparatus, but no definite decision is expressed in the absence of silver impregnation, juxta-nuclear position or indication of dictyokinesis. Though there is evidence that in some flagellates and ciliates the parabasals and excretory apparatus show resemblances to the Golgi apparatus of Metazoa, "yet we can point to no cell inclusions which are similar in all and agree with all the criteria for the metazoan Golgi bodies. Possibly in some cases, e.g. *Opalina*, the Golgi apparatus is in a somewhat elementary condition, and the parabasal apparatus may also represent a not wholly differentiated Golgi apparatus."

Fungi causing Human Blastomycosis. A very interesting paper entitled "Observations on Fungi isolated from Cases of Blastomycosis cutis and Blastomycosis pulmonalis in North America and Europe. Remarks on Blastomycetin" appears in the *Journal of Tropical Medicine and Hygiene* of October 16. The authors are Sir Aldo Castellani and Prof. Igino Jacono, who publish photographs to show the almost terrifying severity of blastomycetic ulcers upon the human skin. The fungi which cause the diseases have been studied with a detail worthy of Sir Aldo Castellani's great resources. The present paper describes the cultural and microscopical characters of the organisms, but further work on inoculation is also in progress. Representatives of the genera *Torulopsis*, *Monosporium*, *Glenospora*, *Geotrichum*, *Phialophora*, *Acrotheca et al.* have been studied, and most of the species have been described for the first time. Tests have been made with monovalent and polyvalent blastomycetin, in order to see if it has any value for diagnosis.

Absorption of Calcium by *Terminalia glabra*, W. and A. Mr. B. L. T. de Silva, of the Department of Botany, University College, Colombo, in a communication to the Editor, directs attention to the remarkable manner in which *Terminalia glabra*, W. and A., accumulates calcium from the soils of the Miocene limestone of northern Ceylon. The water is usually softer in this area from wells near these trees, and the villagers in the dry zone burn the bark of the tree as a source of lime. In this region the ash of the leaf was 57–61 per cent CaO, of the bark 83–91 per cent. *Terminalia glabra* is a deep rooted tree and may thus remove calcium from the deeper layers of soils whilst its leaves, rotting in the surface layer, may make this layer richer in lime than the leached surface soil out of the range of these falling leaves. Mr. de Silva cites figures of analyses of surface soils in support of this conclusion.

New Zealand Beech Timbers. Mr. Parkham, of the Cawthron Institute, Nelson, has published an interesting paper entitled "New Zealand Beech Timbers: Their Structure and Identification" (*New Zealand J. Sci. Tech.*, 14, No. 4, pp. 233–40; 1933). Beech forests are the dominant associations forming the subantarctic rain forest of New Zealand, and extend from the East Cape district, in the North

Island, down the mountain chains to Cook Strait, and so, too, in the South Island to Foveaux Strait The object of the author's research is to describe the anatomical structure of the secondary wood in order to facilitate the identification of timbers after conversion The species included in the scope of the present report are *Nothofagus Menziesii*, *N Fusca*, *N. truncata*, *N cliffortioides* and *N Solandri* The paper contains interesting data concerning the reactions of these beeches during seasoning, their supply, and a variety of commercial purposes for which they are suited The author points out that there is a great tendency to warping, which is less marked in the silver beech (*N. Menziesii*) For some years silver beech timber has been exploited to a considerable extent locally, the annual production being about 8,000,000 superficial foot It is used mainly for general building and constructional purposes, for box-making (butter boxes and cheese crates), for cooperage, farm implements, vehicle body-building, furniture, interior finishing and fixtures, and for turnery (Ward, 1929) The author comments on the fact that up to the present very little research has been carried out on these lines, Engler (1899), Solereder (1908) and Garrett (1924) being the only authorities who have published works dealing with this subject Mr Parkham stresses the importance of maintaining the large areas of beech forest which at present exist in New Zealand, both because of the necessity of perpetuating a forest covering on the water-sheds of the many rivers and streams, and also because of the potential commercial value of such areas (see NATURE, 131, 787, June 3, 1933).

Geology of the Society Islands. Bulletin 105 of the Bernice P Bishop Museum (1933) is devoted to a report on the geology of Tahiti, Moorea and Maiao by Howel Williams, who paid a two months' visit to the Society Islands five years ago The group presents an evolutionary series where volcanic cones may be studied in all stages of erosion and where the encircling reefs are revealed in all stages of development A valuable summary is given, supplemented by many original observations, of the geomorphology and petrology of the Islands Discussing the recent movements of the South Sea islands, the author presents evidence that the Pacific floor of this region has been stable for a prolonged period Maximum proved uplifts are 250 ft. for the Marquesas, 800 ft for the Austral Islands, 230 ft. for the Tuamotus and 554 ft for the Cook Islands, there is no indication of uplift for the Society Islands, save the relative change due to the recent fall in ocean level The supposed evidences of submergence based on a study of drowned valleys are regarded as invalid, the effects of a rise of ocean-level following its fall during the glacial period being regarded as providing an adequate explanation Local tilting is no more than is to be expected in islands of volcanic origin. The report is a well-illustrated and fully documented account of a group of islands that still offers a host of problems of fascinating interest

Water-logging the Punjab. The problem of water-logging due to the general rise of the water-table over a large area is discussed by Dr. E McKenzie Taylor and others in "An Investigation of the Rise of Water-Table in the Upper Chenab Canal Area, Punjab" (Research Publication, vol. 1, No. 4, Punjab Irrigation Research Institute). Statistical examination of the figures for well levels, rainfall and irrigation discharge show a high correlation between rise of water-table and monsoon rainfall, but no correlation between rise of water-table and the amount of irrigation water supplied. The rise of water-table and the increase of irrigation are mutually exclusive. Dr. Taylor concludes that the rise of water-table can be controlled by the rapid surface removal of monsoon rainfall and recommends for this purpose the construction of storm-drains Since these deal with surface water they need be of no great depths and would be cheap to construct and maintain Deep seepage drains in the subsoil would also be of use, but would prove costly and do not appear to be a practical solution in an area of rising water-table which is not already water-logged In short, they are not a prevention but merely a cure. Surface drains, on the other hand, should lead to a permanent fall in water-table

Effect of Temperature on Energies of Photoelectrons. The *Physical Review* for December 1 contains two papers by Du Bridge and Hergenrother and by Roehr, on the energy distribution of photoelectrons from molybdenum at different temperatures. In the former paper, the normal component of the velocity of emission was studied by applying a retarding potential between a flat emitter and a parallel plate electrode, in the latter paper the total energy distribution was studied by placing the emitter at the centre of a spherical collecting electrode The emitter was heated by an intermittent current and arrangements were made so that the photocurrent was collected with the heating current off The results were analysed in the light of the theoretical work of Du Bridge based on a Fermi-Dirac distribution of the velocities of the electrons The fit obtained between theoretical and experimental curves was satisfactory The accuracy of the classical determination of h by the application of Einstein's photoelectric equation is brought into question, since these determinations involve an extrapolation of the tail of the photocurrent–retarding potential curve, which is now shown to depend on temperature It appears, however, that the shape of the curve is such that simple extrapolation yields results which all differ by the same amount from the theoretical values at absolute zero of temperature, and the photoelectric determinations of h are probably unaffected by the temperature effect.

Sulphides of Zirconium. The information on the sulphides of zirconium was in an unsatisfactory state and the preparation of three definite compounds, ZrS_2, Zr_2S_3 and Zr_4S_3, by Pichon (*Bull. Soc. Chim*, 53–54, 1269, 1933) has confirmed the existence of the first compound and added two new sulphides to the group The method of preparation was to act on zirconium oxide at a high temperature with hydrogen sulphide. By heating first at 1100°–1200° and then raising the temperature to 1700°, a fused crystalline mass of Zr_2S_3 is obtained. On heating this at 900°–1300° in hydrogen sulphide, the black disulphide ZrS_2 is produced; and Zr_2S_3 on heating at 1400° for two hours in a cathode ray vacuum, or in hydrogen for one hour at 1700°, yields the brown Zr_4S_3 All the products are crystalline. Evidence of the existence of Zr_3S_4 was also obtained. The chemical properties of the substances were examined and it was found that the action on numerous reagents was less pronounced with the compounds containing less sulphur

Auroras, Electric Echoes, Magnetic Storms

By SIR JOSEPH LARMOR, F.R.S.

RECENT reports by E. V. Appleton and his associates, Norwegian and other[1], have brought out the complex connexions between the optical and magnetic phenomena of the upper atmosphere. The considerations that follow touch only the fringe of this interesting subject: but it may be permitted to record them before they pass out of memory.

Assuming waves short enough to permit analysis by ray-propagation, there would be two paths of transit from one place to another not too distant, one straight across, the other by reflection from what has been appropriately termed a ceiling aloft This latter is represented by a caustic surface, belonging to the source supposed of coherent periodicity, at which all the rays are turned back tangentially none can get across it, unless the medium is discontinuous consisting for example of banks of reflecting ionic clouds. Some frequencies have no ceiling, or one only of limited extent. The numerical densities (N) of electrons at the apices of the ray paths, which practically lie along the caustic, are determined at once by the optical law of refraction, that $\mu \sin z$ is constant along a ray; for the directional angle z to the zenith is $\frac{1}{2}\pi$ at the apex, so that the value of μ there is $\mu_0 \sin z_0$ for the position of the observer Unless the direction of emission is at very small angle (z_0), μ is thus a moderate fraction of the initial value μ_0, about unity, at the level of emission Either then N at the apex is a moderate number, rather less than for vertical reflection as *infra*, or else z_0 is very small so that all the rays that reach the ceiling start off nearly vertically and bend sharply, or else the analysis by rays is not applicable to the lengths of waves concerned.

It has been found, without doubt, that rays are returned straight back along the vertical path, the highest point of the gradually sloping caustic surface being as above overhead Its exact position can scarcely be determined: but certainly the plane for which μ vanishes—the velocity of propagation there becoming infinite or the medium optically rigid—which is readily estimated, lies beyond the caustic The familiar formula for frequency $p/2\pi$ and electrons of mass m,

$$\mu^2 = \mu_0 - \frac{4\pi N e^2 c^2}{mp^2}, \quad \frac{p}{c} = \frac{2\pi}{\lambda}, \quad \frac{e}{m} = \frac{7}{4}\cdot 10^7, \quad e = \frac{3}{2}\cdot 10^{-20},$$

gives, for N per cubic cm. and λ in cm, $\mu^2 = 1 - \frac{5}{6}10^7 N\lambda^2$ Thus for waves of the order of 300 metres, μ^2 would vanish when N has risen to the moderate value $\frac{1}{7}10^5$, and for 30 metres to $\frac{1}{7}10^7$ The intensity of ionisation which thus arrests propagation by waves is small, perhaps much beyond expectation. This does not, however, mean that a cloud of ions, of diameter more than a few wave-lengths, would collapse by any essential instability. Vanishing index means that the medium is electrically absolutely rigid for these lengths of waves, so that disturbances of such length could not get into it at all, would be turned back or in part smothered: infinite index, as *infra*, would mean that it is flaccid, with like results: this now holding good whether treatment by rays is applicable or not, thus in this rough estimate avoiding the complexities of gyro-radiational analysis, as exemplified in S. Goldstein's work[2]. If radiation of various wave-lengths is sent up from the source, each constituent is turned back before the stratum for which N has the limiting value (inversely as λ^2) is reached. This is the foundation on which is based the exploration of atmospheric strata by vertical radiation, as initiated and extensively carried out by Appleton and his colleagues, uncertainties regarding oblique reflections thus not entering into the estimates.

Carrying the analysis further in a magnetic field H_0, in the simplest case for the two cyclic waves ($+H_0$ and $-H_0$) travelling directly along H_0, the expression for μ^2 involves in the denominator $mp^2 + eH_0p$ instead of mp^2 One of the two waves becomes obliterated by μ^2 trending to infinite value, so that the velocity fades to nothing at a stratum where p or $2\pi c/\lambda$ has fallen to $\frac{7}{4}\,10^7\,H_0$, which for values of H_0 of the order of the earth's magnetic field would be when λ is more than half a kilometre The radiation which gets through is then solely the conjugate cyclic component Here N does not occur at all in this estimate but that could not mean that even a very sparse distribution of electrons would prohibit one set of component waves if the impressed field H_0 (or rather $H_0\lambda$) were great enough. It means that there could not be cyclic radiation of this kind with what few electrons there may be present playing a part in it; this is because in circular orbits such as they would have to follow the centrifugal reaction mp^2r could not adapt itself to compensate the electrodynamic force eH_0r, and therefore such participating orbits could not subsist · but when the number of ions is small cyclic radiation can travel in the ordinary manner, only slightly disturbed by their irregular motions

Specially close connexion of magnetic storms and the Aurora Polaris with anomalies in wireless radiation is reported by Appleton. This contrasts, of course, with the extremely subordinate influence of magnetic fields on the short waves of physical optics, except for ferromagnetic metals. A conceivable presumption would be that the aurora is due to lasting local pulsations on a large scale, so of long period, excited somehow by a local cause large enough and of abrupt type, produced conceivably by arrest high up of an ionised torrent from outside sufficiently concentrated to require relief by propagation in waves the incidence of such long undulations on the molecules of the lower rarified atmosphere could produce the light of the banded auroral curtains. As these bands lie along the direction of the magnetic field this would imply facility of spiralling transmission along that direction. Probably also it has been already explored whether the auroral light shows traces of circular polarity.

Long ago the ascription of terrestrial magnetic changes to electric currents circulating in the upper atmosphere was in favour[3], until the recognition that all currents are made up of convections of ions disturbed that view by the high electron densities implied Yet there seems no help for it if atmospheric ionic views are to be persevered with: thus in recent careful discussion, S. Chapman[4] has not been deterred from densities even up to 10^{10} electrons per cubic centimetre in positions very far up in the abnormal atmosphere. The superior mobility of the negative electrons is there the dominating influence, for compensating positive must be present.

An arresting feature of Prof. Appleton's pairs of fragmentary graphs, giving heights of reflection in terms of frequency, as directly observed, such as may be on his view connected with the two cyclic components into which the radiation is split by the earth's magnetic field, is that though of irregular form, they show rather close repetition of features, differing mainly by a shift along the axis of frequency This suggests search for an analytical correspondence between them, which it is not hard to pursue for the simplest illustrative case of radiation along the direction of the magnetic field H_0 The co-ordinates of the graphs are p, giving the frequency $p/2\pi$ of the waves, and the altitude z of the reflecting layer estimated by the rough criterion of vanishing index μ. More generally, N being some assigned function of z, the graph may relate to any constant value of μ or c/c' The equation of propagation (cf my "Math and Phys Papers", vol 2, p 651, as alone here accessible) is, if φ denotes the single complex electric variable $P + \iota Q$ and d/dt is ιp,

$$-\frac{d^2\varphi}{dz^2} = Kc^{-2}p^2\varphi + \frac{4\pi cNp^2}{mp^2 - 4\pi cH_0 p}\varphi$$

This type of differential equation is familiar for other modes of waves, and has been tractable for some special forms of N as expressed in terms of z When, however, N changes not too rapidly with z, a simple harmonic type $e^{\iota pt - \iota nz}$, so that $d^2\varphi/dz^2$ is $-(\mu/c)^2\varphi$, is a first approximation and, φ dividing out, gives μ^2 in terms of p and N Transition is made to the conjugate wave train by change of sign of H_0 To explore correspondence of the types indicated, we restrict to the case of μ nearly vanishing, when

$$N = \frac{Km}{4\pi ec^2}\left\{(p + p_0)^2 - p_0^2\right\},$$

where p_0 is $2\pi cH_0/m$, being half the critical frequency above described Only in the circumstances of short waves is p_0^2 small compared with p^2 and roughly can be neglected then N is determined by $p + p_0$, and the graph for (N,p) is merely displaced opposite ways from a central position by adding $+p_0$ or $-p_0$ to the abscissa p according to the sign H_0. But the actual graphs belong to long waves

In the next simplest case, when the magnetic field H_0 is transverse to the waves (*loc cit*, vol 2, p 655, where some misprints are to be set right), the displacement of the graphs now involving $(p_0/p)^2$, would be large for a magnetic long wave (The condition for μ to vanish then takes a simple form $Lp = \pm N$) The actual case, that of field oblique, along the line of magnetic dip, would be nearer the former though intricate, it may possibly be worth the trouble of exploring, if that has not already been done by Goldstein (*loc cit*) Down to the higher atmospheric density of the auroral levels the incident electron streams could scarcely penetrate.

As Appleton originally suggested, and is confirmed by Ratcliffe's records, the upper reflection is probably due to an independent layer, and both reflections can be split by the magnetic field in a manner to which this analysis applies

By good fortune, however, the magnetic complications here described appear largely to compensate themselves A cyclic wave-train of dextral chirality going up would be returned as a train of the same chirality, in absence of a magnetic field. imposing the earth's magnetic field would affect them in opposite ways: thus so far, if there is no error here, the magnetic delays in ascent and return should cancel, provided they are along the same path, so that there would be no delay on this ground in reception between the two cyclic components of a wave-train the actual delay would arise from their reflection being at different levels, and would afford a measure of the interval, and thence of the difference in electron density The conjugate cyclic polarisations, each *received* reversed, would remain as a test whether the splitting of the beam is of magnetic type

A reflecting layer would have to be fully established in a fraction of a wave-length, thus rather abruptly for short waves. Thus it would have to fade away more gradually above to avoid thin-plate phenomena: this and the much larger density N that must be attained notwithstanding for short waves may provide clues for exploration

The unexpected result, that whether a magnetic field be present or not, a quite small density of ions entirely upsets the optical elasticity of space as regards long waves, provides a cause preserving ionised gaseous clouds of astronomical size, for example in the interiors of stars, from rapid dissipation or dispersal in bulk; in fact saves an ionised region from lapse to uniformity by internal radiation.

The description[2] of a recording apparatus developed by J A Ratcliffe and E L C White has just attracted my notice The automatic photographic records, of which examples are printed, convey a sense of actuality to which mere verbal description could scarcely attain The continuous run shows the intervals of time during which double reflections are present, and the heights, sometimes very great, from which they appear to arrive We may thus know in time as much about the earth's upper atmosphere as we seem to know about that of the sun The abrupt changes in vertical atmospheric structure recorded in crossing sunset and sunrise meridians agree closely with the early suspected cause of the related disturbances in long-distance signalling

As regards the rather uncertain concept of group-velocity (cf *loc cit*, vol 2, p 546), so familiar for a long time in hydrodynamics, it is an affair, as Hamilton first described it, of an *unlimited* train of regular waves with humps of increased amplitude at intervals, which travel through the waves with a velocity of their own, dp/dn as against p/n for the basic waves These humps do not constitute a train of waves of the same type, for their average amplitude would be null, though they could be receivable as in wireless practice by different apparatus It may not be too wild to imagine a permanent train of waves sent out and encountering a dispersive region in which the group velocity approaches zero owing to very sharp curve of dispersion, so that these humps remain nearly stationary, but when the train on which they ride is terminated, they relieve themselves by propagation forward and backward. but in any case these are scarcely the circumstances of the alleged echo of long delay

V. M. Slipher reports regular occurrence of flashes of auroral spectrum at sunrise and sunset. One can conceive an upper stratum ionised by the solar radiation, and a lower by the long electric waves that can disturb electric reception

These long atmospheric waves would be indicated by disturbed electric reception, but they would not affect the magnets; that would be due to the vast exciting torrents of solar electrons flashing past the earth and partly arrested aloft. They would require a compensating fall into the sun (perhaps spiralling in the sun's rather strong magnetic field) and, as it would be at slower velocity, there would be a solar electric charge. Yet, as I understand, G E. Hale could not find any trace of Stark effect of resulting solar electric field. which would be adequately explained if the electric charge, being of course a surface sheet, lies outside the layer which emits the light The penetration of the cosmic radiation, if it carry a charge, or part of it, into the earth has been in like manner assigned as a cause maintaining the earth's electric charge[6]. by the usual estimate it would have to replenish the static charge of the earth every ten minutes The spatial density of compensating charge falling back into the sun would be considerable if it fell slowly but there is scarcely ground for connecting the fixed spectral lines of some double stars with an atmosphere of that kind. This principle of emission in one mode and compensating absorption in another, is far-reaching · thus it is the foundation of the Einstein theory of radiation by projected and absorbed 'photons'

The characteristic feature of the modern spectral theory, expressing itself in sporadic transitions between energy levels, is that, while it aims at inclusion of the Hamiltonian dynamical analysis, each line has its own configuration of the source, without any overtones such as were a necessary part of a vibrational theory. The equation of Hamilton-Jacobi and the related one of Schrödinger would belong not to an atom but to a cosmos, thus coming into line towards the various universal modes of statistics In asymptotic limit[7] (λ large) the two schemes, Hamilton's (generalised) rays and Schrödinger's potential, come into agreement

Anniversary of the Asiatic Society of Bengal

ON January 15 the Asiatic Society of Bengal celebrated the 150th anniversary of its foundation by an afternoon conversazione in the Indian Museum, and a banquet in the evening followed by a special anniversary meeting The conversazione was attended by the Mayor of Calcutta and about five hundred of the leading citizens of Calcutta It took the form of a garden party on the lawn of the Museum and special and interesting collections of exhibits, consisting of paintings lent by the Academy of Fine Arts, copies of old documents from the Imperial Records Department, mostly of the eighteenth century and some concerning the Asiatic Society, paintings of plants from the Botanical Survey, Javanese and Siamese sculptures lent by Dr S K Chatterji, chemical and physical demonstrations arranged by the University College of Science and Technology, prehistoric and tenth century finds from the Archæological Survey, fossils, crystals and economic products from the Geological Survey, birds of Bengal lent by Dr S C Law, demonstrations of the prevention and treatment of disease arranged by the School of Tropical Medicine and Hygiene, medals and coins by His Majesty's Mint, Kaffir attire, fish, Crustacea and insects from the Zoological Survey

The banquet was honoured by the presence of His Excellency Sir John Anderson, Governor of Bengal, who is the patron of the Society, and took place in its one hundred and twenty-six year old hall, surrounded by portraits and busts of former members who have made history in Bengal Ninety-three members and guests were present, including the consular representatives of France, Germany, Holland, Sweden and the United States of America, the Archbishop of Calcutta, the Hon Sir M N Roy Chowdhury, Sir David Ezra, the Hon. Nawab K. G M Faroqui, Sir C. C. Ghose, the Hon Sir A K Ghuznavi, Lord Sinha, the Hon Sir B P Singh Roy, and Sir Jadu Nath Sircar The toast of the guests was proposed by the president of the Society, Dr L. L. Fermor, to which M J. Delacour, of the National Museum of Paris replied, and also proposed the Asiatic Society, but speeches were brief, in view of the meeting afterwards.

At the special anniversary meeting, His Excellency the Governor took the chair and the president delivered his anniversary address, outlining the history of the Society, and naming the distinguished contributors to its publications, more especially in the last half century He pointed out that many of the specialist departments and institutions founded in India originated from the Asiatic Society, in particular the Indian Science Congress, and mentioned the proposals which had been made for the formation of an Indian Academy of Sciences to affect co ordination between these various interests in the sphere of science

Following the president's address, congratulatory messages were read from His Excellency the Viceroy, the Mayor of Calcutta, the League of Nations, Prof C Rockwell Lanman, Sir George Grierson and Sir Thomas Holland (honorary fellows) Seven addresses were read, from the British Museum, the Linnean Society, the Zoological Society of London, the Batavian Society of Arts and Sciences, the Indian Institute, Oxford, the Schopenhauer Society, Frankfort, and the Prussian Academy of Sciences Congratulations were presented by 26 delegates from 58 learned institutions, and in all 19 countries were represented—Australia, Austria, Belgium, Ceylon, Canada, France, Federated Malay States, Germany, Great Britain, Hungary, Italy, Japan, Netherlands, Spain, Sweden, Switzerland, Tasmania, United States and India

Twelve honorary anniversary members were elected—six in letters and six in science. Prof. Arthur Christensen of Denmark, Prof. Taha Husain of Cairo, Sir John Marshall, lately Director-General of Archæology in India, H R H Prince Damrong Rajahubhab of Siam, Dr. Rabindranath Tagore, Dr J Van Kan, law member of the Council of the Viceroy of the Dutch East Indies, Sir Sidney Burrard, lately Surveyor-General in India, Prof Albert Einstein, Sir Sven Hedin, Prof Alfred Lacroix, Dr. Henry Fairfield Osborn and Lord Rutherford.

In his speech, His Excellency the Governor stressed the vigour of the Society in spite of its age, its permanence since the days of the French Revolution, and the esteem in which it is held abroad, as manifested by the spontaneous tributes received from all over the world. He directed attention to the traditional connexion of the ruling princes of India with the Society, and hoped that this tradition might be widened, to the benefit of scholarship, by the inclusion in the Society's list of members of the name of every substantial ruler in the country.

His Excellency paid special tribute to three members of the Society, Sir Rajendranath Mookerjee, Mr. John Van Manen (general secretary) and Dr. S. L. Hora (honorary secretary of the Celebration Committee).

Research in the British Post Office

WHEN the State purchased the telegraphs in Great Britain in 1869, the number of electrical workers in the whole country could almost be counted on the fingers. To-day the engineer-in-chief of the Post Office controls a staff of about 30,000 and maintains plant of a value of 130 million pounds. Starting from the needle instruments, skilled Post Office experimentalists developed the Wheatstone transmitter and receiver; instruments capable of operating up to 300 words per minute.

Capt. B. S. Cohen, the engineer of the Post Office Research Station at Dollis Hill, in a paper read to the Institution of Electrical Engineers on February 1, said that these instruments still stand unsurpassed to-day in their design, workmanship and performance. It was not until 1912 that a research section was established. During the War period, the thermionic valve was perfected and at one stroke opened a boundless vista of possibilities in the way of universal telephone communication. The paramount necessity was to obtain the closest co-ordination between the research and the operating organisations. Without full access for research purposes to the working telegraph and telephone plant, the work of the research engineers would have been immensely increased. The Research Station at Dollis Hill was started in 1921 by using ex-army huts, and the permanent buildings were completed last year. Much excellent work has been done at this station which could not have been done elsewhere.

To the research workers at Dollis Hill the increase in the volume and weight of road traffic brought with it a new problem. There are apparently under the streets an ever-increasing number of cracked gas mains. Modern road surfaces make it difficult for this gas to escape into the open and so it sometimes accumulates in Post Office cable ducts and manholes, involving a serious hazard. The research engineers have developed a simple form of gas detector for general issue to Post Office workmen. The detector operates in a way somewhat similar to a photographic exposure meter. It utilises a filter paper moistened with a few drops of palladium chloride solution and will indicate the presence of 0·05 per cent of carbon monoxide, the dangerous constituent of coal gas.

The capital value of automatic switching apparatus installed in exchanges is now very large, and great precautions against corrosion have to be taken. Sir Robert Hadfield has said that the corrosion of iron and steel alone costs the world 700 million pounds per annum. Experiment shows that the life of galvanised iron stay wire is proportional to the thickness of the galvanising. In some parts of south Lancashire, the normal life of a stay wire is little more than two years. It is now possible to estimate the life of any particular grade of wire in a given area.

In long telephone lines the 'echo' used to be very troublesome but the engineers have invented, using valves only, a very efficient echo-suppressor. A non-reflecting room at the Station has linings of cotton-wool one foot thick. This room has a totally silent background of noise. It is especially useful for listening tests where the threshold of hearing has to be found.

University and Educational Intelligence

CAMBRIDGE.—At St. John's College, one Strathcona research studentship of the annual value of £150 and two Strathcona exhibitions of the annual value of £40 are offered for competition amongst research students who are graduates of any university other than Cambridge. The election of a candidate not yet a member of the College is subject to his being accepted by the University as a research student proceeding to the Ph.D. degree and to his commencing residence in October 1934. Candidates must make application to the Senior Tutor, St. John's College, not later than July 1.

LONDON.—Dr. G. P. Wright has been appointed as from March 1 Sir William Dunn professor of pathology tenable at Guy's Hospital Medical School. Since 1931, Dr. Wright has been assistant lecturer in morbid anatomy and curator of the Museum at University College Hospital Medical School and also pathologist to the Hospital.

It is expected that the new British Postgraduate Medical School at Hammersmith will be opened to students in October next. It has been given recognition as a School of the University for a period of two years, as a temporary measure.

OXFORD.—In presenting Miss Ethel Bellamy for the honorary degree of M.A. on January 30, the Public Orator, Mr. C. Bailey, took occasion to remind Convocation of the distinguished services rendered by that lady and other members of her family in the cause of astronomy, and particularly in the important part taken by the Oxford Observatory in the photographic survey of the heavens. In consideration of the recent help accorded to the Vatican Observatory towards the completion of that work, the Pope has bestowed on Miss Bellamy a decoration of silver.

ST. ANDREWS.—The Court has agreed to institute a lectureship in bacteriology in the University and has appointed Mr. James F. Murray, who has hitherto been assistant to the professor of bacteriology, to the lectureship as from February 1; Mr. A. B. Stewart has been appointed to succeed Mr. Murray as assistant in the Department.

THE booklet on the new buildings of the University of London, edited by T. Ll. Humberstone and published by the Dryden Press (see NATURE, June 24, 1933, p. 903) has been withdrawn from publication and replaced by a similar book containing also a report of the stone-laying ceremony by the King on June 26. This is published by Mr. William Rice, 3 Ludgate Broadway, E.C.4, at 2*s.* 6*d.*

Science News a Century Ago

Ericsson's Caloric Engine

In 1833 John Ericsson, the famous Swedish engineer, patented a form of hot air engine and his invention formed the subject of a lecture by Faraday on February 14, 1834, at the Royal Institution Referring to this lecture, the *Mechanic's Magazine* said that "after the very favourable opinion we expressed of this invention it gave us no ordinary pleasure to hear it so well spoken of by so eminent authority, in all matters of science, as Dr Faraday He pronounced the theory on which the engine was constructed to be philosophically correct, and the arrangements for turning it to a practical account to be at once novel and ingenious, but expressed some doubts as to whether sufficient provision had been made for preserving that regular alternation of pressure which is necessary to keep the pistons in motion" In Church's "Life of John Ericsson", (vol 1, p 75) it is said "Just as Faraday was preparing to appear upon the platform he came to the conclusion that he had made a mistake as to the principle of the expansion of air upon which the action of the machine depended He accordingly commenced his lecture, greatly to the disappointment of Ericsson, by the announcement that he was unable to explain why the engine worked at all" According to the *Mechanic's Magazine*, Ericsson was not at the lecture owing to illness

Great Lenses in One Piece

"At the meeting [on February 14] of the Royal Society of Edinburgh . . three splendid polyzonal lenses were exhibited by permission of the Commissioners of the Northern Lighthouses One of these was made in Paris, another in London, and the third in Newcastle The diameter of the outer zone of two of these lenses is 2 feet 6 inches, and that of the London instrument is three feet Their focal distance is about three feet. At the desire of Mr Robinson, the Secretary, a single argand burner was placed in the focus of one of the lenses, but the effect was feeble, as this instrument requires a powerful light By exposing it to the rays of the sun it suddenly melts pieces of copper and other metals placed in its focus The Newcastle lens is made of one piece of highly polished glass Buffon, nearly a century ago, first suggested the idea of a polygonal burning glass, but the construction of this instrument has till now been considered beyond the skill of the artist, and the method of building them in separate pieces was afterwards suggested and practised . . in this country and in France. Messrs Corkton, however, the plate glass makers of Newcastle, at length triumphed over the difficulties which so long retarded the execution of Buffon's project. These lenses are about to be removed to Gulland Hill, where their effect will be fully tried, along with the light invented by Lieut. Drummond, from the experiment rooms of the Northern Lighthouse Board" ("Annual Register", 1834)

Liverpool and Manchester Railway

In the *Mechanic's Magazine* of February 15, 1834, is an article on the half-yearly report of the Liverpool and Manchester Railway, for July–December 1833. There had been a very considerable increase in traffic and a dividend of 9 per cent had been declared The total number of passengers booked had been 215,071 and the total quantity of goods carried 98,247 tons, beside 40,134 tons of coal The number of trips of 30 miles performed by locomotives with passengers had been 3,253 and with merchandise 2,587 The figures showed an increase in the number of passengers of 32,248 and an increase in the weight of goods of 11,405 tons The winter had been very wet and stormy, there had been great difficulty in keeping the railway in good order and the boisterous weather and the dirty state of the rails had impeded the passage of the trains; "assistant engines had frequently been required to ensure their progress even on the level parts of the way" Among other items mentioned was that gas coke was being tried in the engines in the place of Worsley coke at a cost per ton of less than a half.

Death of Lionel Lukin

On February 16, 1834, Lionel Lukin, one of the pioneers of the lifeboat, died at Hythe, Kent, at the age of ninety-one years Born at Dunmow, Essex, on May 18, 1742, Lukin became a London coachbuilder having premises in Long Acre, where he continued in business until more than eighty years of age Fertile in invention and with scientific leanings, he invented an adjustable bed for invalids, a raft for rescuing persons from under ice and a rain gauge For a long period he kept a daily meteorological record His experiments with boats were begun in 1784, when he altered a Norway yawl and tested it on the Thames The following year he obtained a patent for his "unsubmersible boat". His claims included a method of construction for either sailing or rowing boats which would neither upset in violent gales nor sink if accidentally filled with water He proposed to fit projecting gunwales, either hollow or filled with cork, together with watertight compartments at the stem and stern and under the seats, which would contain air or cork. His invention was submitted to many distinguished men and was tried at Ramsgate and Margate He had, however, to contend with seafaring prejudices and his boats were in little request A description of them was published by him in 1790 Lukin's invention was almost contemporary with that of the Shields boat-builder, Henry Greathead (1757-1816), through whose work lifeboats were introduced in the north of England

Royal Society Fellowship, 1834

One hundred years ago there was practically no restriction as regards the number of fellows that might be elected in the course of the regular meetings of the Royal Society A statute, enacted in 1831, provided that no election for fellows or for foreign members should take place excepting on the first ordinary meetings of the Society in December, February, April and June. This remained in force until 1835, when it was repealed In 1847 the plan of electing fifteen fellows annually became the rule, and in 1930 the number was increased to seventeen The following were elected in February 1834. Capt Francis R. Chesney, Thomas Copeland, Sir Edward Cust, James Horne, John Russell Reeves, Lieut.-Col. William H. Sykes, John Waterhouse No foreign members were elected during the year 1834.

The custom of holding no meeting on the anniversary of the death of Charles I lapsed after January 30, 1834.

Societies and Academies

London

Royal Society, February 1 A K Denisoff and O W Richardson The emission of electrons under the influence of chemical action This paper starts by summarising some general conclusions reached from experiments on the reaction between K_2Na and 22 different gases A more refined and detailed experimental investigation than has hitherto been carried out with phosgene is then given This is followed by a discussion of the low energy part of the spectrum, the determination of the true zero on the volt scale and of E_m (maximum energy found from the energy distribution curves) and its relation to E_c (energy of corresponding elementary chemical reaction responsible for E_m) The last section confirms the equation $E_m = E_c - \varphi$ (work function of the metal) for the particular case of $COCl_2$ Sir Robert Robertson, J J Fox and A E Martin Two types of diamond From an observation that a diamond failed to give a prominent absorption band at 8μ in the infra-red region of the spectrum where a great number of diamonds gave this, a similar exploration was undertaken in the ultra violet region, where a difference in absorption in the same sense was found More examples were found and two types were recognised, the more common or opaque Type 1 (band at 8μ and complete absorption at λ 3,000), and Type 2 (no band at 8μ and complete absorption at λ 2,250) Other properties were investigated Type 2 was found to be more isotropic optically than Type 1, but there was no difference in specific gravity, refractive index and dielectric constant between the types , or in the Raman effect, which gave one fundamental frequency at 1,332 cm^{-1} for both types From the complete band system in the infra-red (to 17μ) and the new carbon bands found about λ 3,000 in the ultra-violet, together with the Raman frequency, a picture is sketched of the various modes of vibration of carbon against carbon in the diamond structure, for which the frequency of the fundamental vibration is also calculated While most diamonds give some response to light when the passage of the dislodged electrons is assisted by an applied potential, some diamonds (of Type 2) generate a current without the application of any voltage When these diamonds have been activated by light of λ 2,300 they acquire a condition in which light of certain wave-lengths can quench the photo conductivity while others augment it

Paris

Academy of Sciences, December 26 (*C R* , 197, 1705–1784) The president announced the death of Charles Porcher, *Correspondant* for the Section of Rural Economy E Jouguet The theory of critical phases The generality of the properties of zero area.   Evolution of the Mind. By Prof. G. Elliot Smith, F.R.S. 245

Peace and War

RECENT events have suggested that the modern organised State, closely linked as it is with the highly emotional concepts of the new nationalism, might prove a danger in the way of the free pursuit of scientific inquiry, and that it has already affected the international standing of science It may be argued with equal justice that such a State is also a menace to the present nicely adjusted equilibrium of forces between the Powers which we call by the name of peace The responsibility for the feeling of instability in the present international situation, of which every nation is conscious, is to be attributed, not so much to the activities of Herr Hitler and President Roosevelt in the political and economic fields—though these may seem to run counter to any progress towards a solution of world-wide problems on a world-wide basis—as to the spirit of aggressive self-expression and integration characteristic of present-day nationalism This spirit emphasises and glorifies national distinctions, oblivious of the consciousness of a common humanity, to which much is forgiven and in which differences are composed rather than made the cause of offence By the stress laid on nationality the urge towards the larger unity is repressed.

Many have asked why mankind for ages should have lived under the constant menace of war. War has been sung by the poets and glorified by the historians, and for certain individuals, and perhaps even to whole hordes which have been dignified by the title of races, the career of arms has represented the fullest expression of man's essential nature. Yet it may be questioned whether the adventurous spirit and the joy of battle are commonly the obstacles in the way of peace they are sometimes said to be, especially when the conditions of modern warfare are kept in mind

If there is one thing that may be affirmed with certainty to-day, it is that a majority of the nations of the world do not desire war. Yet all are watching anxiously for the spark which may light a conflagration destined in all probability utterly to destroy the civilisation of the western world, and beyond disarmament no suggestion is put forward as a remedy. It is, therefore, all the more an urgent necessity, as Lord Raglan points out in his recently published book, "The Science of Peace",* that the underlying forces operative in bringing about wars should be understood. For neither pacifists nor the League of Nations will ensure peace until the factors by which it is endangered have been eliminated, even though the facile argument of despair may reiterate its belief that the situation is brought about inevitably by man's instinctive tendency to pugnacity

---

* The Science of Peace. By Lord Raglan. Pp. x+165. (London. Methuen and Co, Ltd., 1933.) 5s 6d net

Modern Germany—unfortunately specific reference in this context is inevitable—has glorified and idealised war Although the Chancellor has expressed his devotion to the cause of peace, and the recently concluded agreement with Poland, which apparently would eliminate the Polish Corridor as a *casus belli* for a period of at least ten years, is an earnest of good intention, nevertheless the youth of Germany is disciplined in the belief that war, rather than peace, is the arena for the fullest exercise of civic virtue, as well as the noblest training ground of the citizen A warlike and aggressive spirit which fights blindly for its tribe is displayed for emulation as the Aryan's virtue If by 'Aryan' we are to understand 'Nordic', as presumably we must, it is a strange turn of the wheel that has made a nation, which only a short while ago claimed to have led the world in philosophy, science and certain branches of the arts, now seek to mould itself on the pattern of peoples who were the destroyers and not the founders of civilisations But neither physical nor cultural anthropology endorses the exclusive ideal of 'Aryanism' as having a basis in historic fact , and a patriotism which pursues its end without regard to considerations of logic or common sense may in the long run be as destructive of the Fatherland as treason. For good or for evil, Germany affirms her belief in the struggle for existence as a conflict among nations, and in survival as determined by the arbitrament of war

The fighting qualities of the Nordics cannot be quoted in support of any theory of the innate pugnacity of primitive man, for they were barbarians rather than primitive Dr W. J Perry has collected a considerable body of evidence to show that the peoples of the lower culture are essentially peaceable, and Lord Raglan accepts this view, while pointing out that organised aggressive warfare begins at a later stage of social development, in which ritual ceremonial requires a periodical, and often considerable, supply of captives to provide for human sacrifice. There are others, however, who view the primitive state and the evolution of man at a different angle The life of primitive man, like that of modern man, is many-sided, and each observer is apt to regard it from the point of view of his own special interest

Sir Arthur Keith, for example, essentially a Darwinian, like Hobbes of 'Leviathan' fame, sees Nature as a state of war. For him the advance from primitive to civilised has been achieved in a struggle for existence by which peoples have been welded into nations—races in process of becoming Warfare, in fact, he holds, is one of the forms of machinery whereby Nature works in the satisfaction of a biological urge towards the establishment of the more highly specialised type, a position which it must be admitted is not unlike that of Hitler himself Here indeed the difference between Sir Arthur Keith and Lord Raglan becomes most apparent, for while the latter, viewing the situation as a social anthropologist, arrives at the conclusion that the obstacle in the way of peace and of peaceful mindedness in the peoples of the world to-day is the concept of nationality, Sir Arthur sees in the nation a stage, achieved by struggle, on the way to peace—to be more fully attained by the apotheosis of the nation in a federation such as the British Commonwealth of Nations

It may seem that Sir Arthur Keith's patriotic enthusiasm for the British Empire has warped his sense of logic , but the fallacy is formal rather than material. If we could look on the hideous slaughter, the cruelty and brutalities of war, which have disfigured the history of mankind, with the same detachment as we view the survival of the fittest among the millions of the lower organisms, would it be possible to say that the results of war have not been beneficial and in the long run have conduced to the advancement of mankind—as, for example, in the conquests of Alexander and Julius Caesar ? To deny it would be to affirm that the peoples then drawn into the main stream of history would have developed along lines equally or more conducive to progress without the intervention of conquest—a contention incapable of proof, however high may seem the degree of its probability. On the other hand, to admit the validity of the argument is not to deny the advantage, indeed, we may even say the necessity, of peace for the future War has become an anachronism, in which the wastage of life and material are more than the belligerents, and often in these days of universal reactions, more than the world at large, is able to endure

The predominant characteristic in modern civilisation is its constant advance towards a more complete scientific understanding of conditions in all departments of human life It would be an ironical commentary on man's ability to control the material conditions of existence if he were unable to understand and guide forces within himself which threaten him with destruction.

The one essential factor is not so much the elimination of the causes which have led, and may still lead, to war, though naturally this has its importance, as the creation of a peace which is a habit of mind among peoples and not as it now is, a state of unstable equilibrium, maintained by the sanction of force, in which the nations are on the alert for the outbreak of war.

How this habit of mind is to be attained is a problem which should not be beyond the possibility of solution Obviously that solution does not lie in disarmament alone Disarmament, however attractive in theory, may become a forcing house for jealousies, rivalry and suspicion Nor does experience endorse the claim of the League of Nations If we may rely upon the evidence of man's social development in the past, it would seem that we must look rather to a general and widely-distributed consciousness of group-solidarity ; but it must not be the narrow group-consciousness of 'nationalism' The *Pax Romana* is an obvious analogy The *Pax Romana* endured in the consciousness of a common citizenship which embraced all but the outer fringes of the then known world. The studies of the social anthropologist tell us of the homogeneity which rules within the primitive social group. He shows us how its extension may be followed in the development of the social organism by aggregation as family group merges into tribe, tribe into people and people into nation Within these groups and between their members, as a normal condition, there is peace. Broadly speaking, and in general terms, this has been the rule in the modern State. Only on rare occasions has social unrest produced disturbance sufficiently serious to amount to war.

It is obvious that the larger the proportion of the world's peoples to be brought within the political unit, the greater the possibilities of a permanent peace. By 1914 the nation, in the traditional form in which it had existed in the previous hundred years, had outgrown its utility in relation to the needs of international politics, commerce and finance. It was this which, by restricting Germany's power of expansion, was in part responsible for the War of 1914–18 , and now, after that War, the problem of peace is even more closely bound up with the necessity for developing some new and more elastic form of political aggregation. We are, as it would appear, moving towards new political forms , but whether in the present temper of the nations they will conduce to peace or lead to a war more catastrophic than the last, seems to be left to blind chance Russia and Italy have each applied a new spirit within old political boundaries, while America, southward of the Canadian line, stands aloof behind the possibilities of a revitalised Monroe Doctrine France in its colonial policy of citizenship for its subject races, and Great Britain in the Statute of Westminster and the inauguration of Dominion status have each made their contribution to the future development of the political organism The crux of the situation is Germany. Will the historian of the future write down the 'tribalism', which would substitute tribal for State boundaries within the Reich and proposes to overleap political frontiers, as a mere reactionary archaism or as a stage towards the formation of a great pan-Teutonic union of the peoples of Central and Northern Europe on 'racial' lines, towards which the approach to Austria marks an attempt to take the first step ?

Goodyer's Dioscorides

The Greek Herbal of Dioscorides Illustrated by a Byzantine A.D 512, Englished by John Goodyer A D. 1655, Edited and first printed A.D 1933 by Dr Robert T. Gunther Pp x+701. (Oxford Dr. Robert T Gunther, 5 Folly Bridge, 1934) n p

IN 1909 the late Canon Vaughan of Winchester, having seen the collection of books on botany bequeathed to Magdalen College, Oxford, by Mr John Goodyer (1592–1664), described Goodyer as "a forgotten botanist of the seventeenth century" The Canon was Rector of Droxford : we know that many of the plants the descriptions of which by Goodyer were printed by Dr Thomas Johnson in 1633 in his revised version of the rather unsatisfactory "Herbal" which Mr. John Gerard (1525–1612) published in 1597, were grown in Goodyer's garden at Droxford. But as one of these plants was the "edible Sunflower", the first tuber of which Goodyer had planted by March 25, 1617, and as Goodyer was able to report on October 17, 1621, that he had already "stocked Hampshire" with "this wonderfull increasinge plant", we know that, whatever may have been the case with botanists, the memory of Goodyer has survived among gardeners interested in the history of their craft. In his introduction to the revision of Gerard's "Herbal", Johnson informed his readers that Goodyer was the friend who had rendered him most assistance in that undertaking, and declared that his friend was "a man second to none in his industrie and searching of plants, nor in his judgment or knowledge of them" The trifling amount of editorial modification bestowed on some of the descriptions with which Goodyer supplied him, suggests that Johnson was as much struck by the judgment his friend showed in recording his observations as by the knowledge these observations had yielded

In the "Sketch of the Progress of Botany in England" published in 1790, Dr R Pulteney (1730–1801), on the authority of Johnson, who died in 1644 of wounds received during the defence of Basing, and of Mr. John Parkinson, who died soon after the publication of his "Theatrum" in 1640, regarded Goodyer as entitled "to the most reputable rank among those who have advanced the botanical knowledge of this kingdom", and added, on the evidence of a "curious communication" which had struck himself, that Goodyer must be inferred "not only to have been what may be called a *practical* botanist, but learned and critically versed in the history of the science"

In 1919 Dr R T. Gunther, as librarian of Magdalen, began an exhaustive study of the books and papers which reached the College in 1665, and in 1922 placed his results at the service of botanists in the charming volume entitled "Early British Botanists" From its pages we learn that by 1616, Goodyer had already begun the formation of a botanical library, that he may have been in personal touch with Johnson in November, 1618; that during the period of June–October 1621, he wrote some ninety descriptions of plants for his friend, and during the next ten years he prepared some thirty more; that Johnson and Goodyer were in London together in November, 1631, and that the one hundred and twenty descriptions he had drawn up for Johnson were sent to his friend in three instalments on March 5, March 12 and March 19, 1632 These facts may explain the origin of the misleading tradition that Johnson revised Gerard's "Herbal" in the short period of twelve months.

Among the volumes Goodyer had already acquired in 1621 appears to have been his copy of the Aldine "Theophrastus" of 1497. By way of relaxation after the spell of descriptive drudgery during the summer and autumn of 1621, he devoted the winter of that year as well as the winter of the following year to the translation, first of "De Plantis", and then of "De Causis Plantarum". Goodyer's English version of "De Plantis" was the only one known to exist until the publication in 1919 of that by Sir Arthur Hort. so far as is known, the manuscript translation in the library of Magdalen College prepared by Goodyer in 1622–23 is still the only English version of "De Causis Plantarum".

Thirty years later, Goodyer began at 10 a.m on April 29, 1652, to prepare an English version of Dioscorides. This task was completed in the forenoon of August 29, 1655, and at 2 p m on that day he began to transcribe the Greek text corresponding with the English translation. This supplementary task was completed on March 17 following and, three days later, at 11 a m. on March 20, he began a translation of the "Scholia" on Dioscorides which A Saracen dedicated to Henri IV and published at Lyons in 1598 In the preparation of the English version of Dioscorides, Goodyer had the assistance, apparently subsidised, of another scholar, possibly his friend and neighbour, the Rev John Heath. That this arrangement subsisted in connexion with the "Scholia" seems clear, that, in this case, the assistant was Heath is almost certain, for the translation of the "Scholia" ended abruptly on October 2, 1656, to be followed by an entry intimating that the Rev. John Heath had died on November 25, 1656. The facts adduced by Dr. Gunther, if they do nothing else, at least show how fully warranted was the inference drawn by Dr. Pulteney in 1790.

In his "Dioscorides. illustrated by a Byzantine: Englished by John Goodyer" Dr. Gunther has now (1934) further safeguarded the "pious memory" of a remarkable Englishman and supplied botanists with a gift that, through no fault of Goodyer, has been withheld for two and a half centuries from those Goodyer wished to benefit. The illustrations bear no direct relationship to Goodyer's version of the text. They reproduce the drawings in the Codex of Dioscorides prepared in A.D. 512 for the Lady Juliana Anicia, daughter of Olybrius, the head of the Anician house who was Emperor of the West for a few months in A.D. 472. Some figures may, it is thought, be copies of plant-portraits approved by Crateuas, a century and a half before Dioscorides became an army surgeon in Nero's reign: some, it is clear, can only be drawings of plants which herbalists contemporary with the lady for whom they worked thought might be those Dioscorides had in mind. In quality they vary from portraits that would do credit to a Renaissance herbal, to caricatures that the editors of the "Hortus Sanitatis" might have rejected.

As Dr. Gunther showed in 1922, Goodyer in his later years took to prescribing for sick domestics and neighbours: it is possible that this new interest may have led him to consult the herbal of Dr. William Turner (1515–1568) and to note Turner's remark regarding an item "whiche a lytle before I have taken out of Dioscorides and translated unto you". In any event, Goodyer in 1652 followed the example of the Dean of Wells and began to translate Dioscorides

The fact that Goodyer translated Theophrastus when he was thirty-two and did not begin to translate Dioscorides until he was sixty-one, is not the only reason we have for thinking that Goodyer was not, at heart, a herbalist A popular work published at Oxford in 1659 shows that the herbalist relied on phytology . "the Art of knowing and finding out the Temperature, Vertue and Use of Plants, as serving to the Curation and Sustentation of the Body" . empirical acquaintance with the qualities of plants determined his efforts at classification and guided his attempts at identification. But in Central Europe the portraits of plants in herbals were gradually becoming more reliable, and in Southern Europe the discriptions of plants were becoming more methodical. As a result it was being realised that it was easier to identify plants by their characters than by their qualities, and though classification by qualities still remained in vogue it was safer to identify plants first and study their qualities after their identity had been determined: Botany, "the Science of knowing and naming Plants" was recognised as a safer guide than "the Art of Phytology".

That Goodyer was a master of method his plant-descriptions show, though he did not, like the Rev. John Ray (1628–1705), employ method as an aid to classification. Nor can we venture to say of Goodyer as the Rev Gilbert White (1720–1793) said in 1771, that "our countryman, the excellent Mr. Ray, is the only describer that conveys some precise idea in every term or word". But we can say of Goodyer what Dr. Gunther's eminent father said, a century after Mr. White, of "a forgotten zoologist of the eighteenth century", that he was "one who recorded, in absolute truthfulness, the results of his own observation and nothing more or else" This trait is as marked in Goodyer's English version of Dioscorides as in his descriptions of plants: he did not, like the Dean of Wells, interpolate his own remarks in the matter translated from Dioscorides, nor did he substitute a synonym for a "caption" selected by Dioscorides himself. For this reason botanists may regret less than scholars must, the fact that Dr. Gunther has not been able to include in his pleasing volume the Greek text of Dioscorides transcribed by Goodyer in 1655 after his English version was finished. That text, which should correspond with the English version, was the result, as Dr. Gunther explained in 1922, of a study of eighteen texts of Dioscorides. Botanists and scholars alike would have been glad of an opportunity to compare the recension made in 1830 by a scholar so eminent as Sprengel with the one effected in 1655 by so competent a botanist as Goodyer For if Rousseau "had reason" when he said that Theophrastus was the one *real* botanist the ancient world produced—other classical authorities on plants being only phytologists—we with equal reason are entitled to say that Goodyer was the first *real* English botanist.

Dr. Gunther can feel assured that botanists are deeply indebted to him for the services he has already rendered them, but he must be prepared to find that they resemble Oliver Twist and that they will appeal to him to favour them one day with Goodyer's English version of "De Causis Plantarum", while scholars will join with them in begging him to give them, if possible, at the same time Goodyer's recension of the Greek text.

Light and Health

The Physiological Effects of Radiant Energy By Prof Henry Laurens (American Chemical Society Monograph Series, No. 62) Pp 610. (New York The Chemical Catalog Co., Inc, 1933) 6 dollars

THE recent widespread interest in the therapeutic effects of ultra-violet radiation has led to the publication of so many original papers, that it is difficult to form any clear picture of the data as yet ascertained. Hence a summary of this type is welcome, and will give many research workers yet another reason for gratitude to the American Chemical Society for the series of monographs of which this is the sixty-second.

The book is confined almost entirely to radiations of medium wave-length, from ultra-violet to infra-red, and thus omits the important but very different effects of X-rays, and those of the relatively long-wave electromagnetic radiations of which the biological application has only begun in the last few years. However, the field covered is quite wide enough for one volume A chapter on the physics and measurement of the radiation concerned is followed by chapters on the effects on the skin, on wounds, on the eye, and on the circulatory system. The effects of radiation on metabolism are given 224 pages of discussion, which include a detailed account of the work leading to the preparation and isolation of vitamin D Later chapters include an account of the striking phenomena of photodynamic sensitisation, and of a study of the results of heliotherapy in tuberculosis The book ends with a useful bibliography of about 900 references

The reader is left with a feeling of disappointment that in spite of so much study, so few conclusions can be drawn with any certainty As the author says in an admirable preface, "Many readers will be annoyed at the inconclusiveness of some of the statements" This is so true that one wishes that the author had added to each section a summary showing what conclusions could be drawn with safety from the rather confusing mass of data presented to the reader Such summaries, if made with the sound judgment shown in the preface and introduction, would have added much to the value of the book

Much of the uncertainty is due to the exceptional difficulties met by research workers in this subject. Physicists, who are accustomed to have some control of the major variables concerned in their experiments, might well be appalled at the difficulties met with in studying such a problem as 'the therapeutic effects of ultra-violet light' In this work, almost the only major variables that can be controlled accurately are the time of exposure to radiation and the sex of the persons receiving it A host of other variables escape control to a greater or less extent, such as the source of radiation, the degree of disease in different patients, the blood supply to the skin, the diet, and even the regularity of attendance at the clinic. All these may form serious sources of error, and it is because of such difficulties that the author can sadly remark, "The real mode of action of radiant energy and its component parts is still unknown".

Modern Research in Astronomy

The Universe Around Us. By Sir James Jeans. Third edition, revised and enlarged. Pp x + 380 + 30 plates (Cambridge · At the University Press, 1933) 12*s* 6*d* net

THE three years which have elapsed since the publication of the second edition of this book have been fruitful in discovery in both physics and astronomy To the two fundamental units of which matter was believed to be composed, the proton and the electron, have been added the neutron and the positron The exclusion principle has assumed great prominence and many investigations have been concerned with the properties and nature of the highly penetrating or cosmic radiation Much attention has been given to the theory of the expansion of the universe and to the question whether the observed rate of expansion, indicating a relatively short time-scale for the age of the universe, can be reconciled with the much longer time-scale which many lines of evidence point to for the evolution of the stars , or whether, on the other hand, previous conceptions must be abandoned and the short time-scale adopted for the stars also

These new problems are all dealt with in the third edition of Sir James Jeans's well-known book, which has been at the same time thoroughly revised The arguments for and against both the short and long time-scales of stellar evolution are discussed in some detail Sir James favours the long time-scale , this time-scale can be harmonised with the observed data as to the velocities of recession of the spiral nebulæ if, as de Sitter has shown, the universe is supposed to be either in a state of pulsation or to have undergone in the past a single contraction from an expanded state, followed by the expansion which is now in progress

The new material makes the present edition substantially longer than the previous editions. The book retains its place as the best account available, in simple language, of the results of modern astronomical research and of their interpretation The book is so free from mis-statements that attention must be directed to the statement on p. 277, repeated again on p. 290, that Nova Aquilæ when at its brightest had an effective temperature of 65,000° It was only in the later stages of its outburst, long after maximum brightness had passed, that Nova Aquilæ or any nova attained temperatures of this magnitude.

Short Reviews

All about Fish and other Denizens of the Seas and Rivers. By W. S. Berridge Pp. 254+63 plates. (London, Bombay and Sydney: George G. Harrap and Co., Ltd., 1933.) 7*s.* 6*d.* net.

MR. BERRIDGE fills his pages with a large amount of interesting information concerning marine animals. There are chapters on fish in general, fish that make nests, the food of fish, luminous fish, electric fish, goldfish, and many other animals including invertebrates such as oysters and cockles, lobsters and shrimps, corals and sponges. The book is amusing and the original photographs are good, sometimes very good, but it is a pity that they do not match the text, for when reading about a basking-shark or a sea-serpent we find pictures of goldfish, and a remora illustrates the remarks on oysters.

Much that is instructive is included in the accounts of the habits and peculiarities of marine animals, some of world-wide distribution. However, there are a few statements which might be altered to advantage. For example, one would certainly infer from the author's notes that *Noctiluca* is rare off British coasts when in reality it is common but erratic in its appearances, and although it is extremely important as a light-giving organism, there are many other minute members of the plankton which may cause phosphorescence, or luminescence, in the sea Again, the British squid may breed in almost any month of the year and not in May and June only, and the pea-crab, which is stated to be fairly common off the Irish coast, may be found in mussels on almost any suitable bed.

Mimicry By Prof. G. D. Hale Carpenter. With a Section on its Genetic Aspect by E B. Ford (Methuen's Monographs on Biological Subjects.) Pp ix+134 (London. Methuen and Co, Ltd, 1933) 3*s* 6*d* net

THIS little book is intended to present the theory of mimicry as developed by natural selection All those who accept the theory and delight in finding new proofs for it will welcome the book, since the author has produced a clear and concise summary of the main facts and arguments in its favour. On the other hand, the treatment accorded to criticisms of the theory is very inadequate, and some of the most serious objections to it are dismissed in a few words; while the opinions of some well-known critics of the theory cannot be found in the text, and their works do not appear in the list of references. The latter is very complete with regard to some authors but it is surprising not to see in it any works except in English. This may create an impression that the mimicry theory has no followers and supporters outside Great Britain. Actually, this is not so, and it would strengthen the case of mimicry if at least the outstanding Continental and American contributions to it were quoted.

Causality: a Law of Nature or a Maxim of the Naturalist? Lecture delivered at the Royal York Hotel, Toronto, on May 14th, 1932, much enlarged By Dr. Ludwik Silberstein Pp. viii+159 (London: Macmillan and Co, Ltd, 1933.) 4*s* 6*d*. net.

As a forceful defence of the principle of determinism in Nature, as against the current interpretations of the new physical theories, this book needs careful thought The author believes that the menace to determinism is rather premature and marks only a provisional stage in the re-shaping of the foundations of physical science A correct interpretation of the principle of causality would show that Nature is not necessarily left to chance. This interpretation consists in considering the principle of causality as a maxim of the naturalist rather than a law of Nature In this heuristic capacity, the principle is used to supplement, with other fragments of Nature, every incomplete system encountered, until it is amplified to a complete, undisturbed whole T. G.

Geschlechtsgebundene und geschlechtskontrollierte Vererbung By Björn Föyn (Handbuch der Vererbungswissenschaft, herausgegeben von E Baur und M Hartmann, Band 1, Lief. 17.) Pp iv+122 (Berlin Gebrüder Borntraeger, 1932) 25.20 gold marks.

THIS is a summary of recent knowledge of sex-linked and sex-controlled, or sex-limited, inheritance, including the recent genetical and cytological studies of sex-linked inheritance in *Abraxas*, *Drosophila*, *Sciara* and *Phytodecta* among insects; *Lebistes* and *Aplocheilus* among fishes, and *Melandrium* among plants. Each case is carefully elucidated, with a free use of illustrations. Many other animals are considered in the special part, and there is a brief statement concerning the sex-chromosomes and sex-linked inheritance in man. A bibliography of twenty pages completes a very useful summary of this field of heredity.

The Aquarium. By E G Boulenger. Pp. 71. (London: *Poultry World*, Ltd., 1933.) 1*s.* 6*d* net.

THOSE who wish to keep a fresh-water aquarium would do well to provide themselves with this little book, which contains a large amount of useful information. First comes the making of the aquarium and the plants which are most suitable for it; following this there are chapters on goldfish, cold-water fish and tropical fish, with notes on the habits, food and proper treatment of each species. These notes are interesting and amusing, and one can learn much from such a short survey. The illustrations, figuring most of the best-known aquarium fish, are by Mr. L. R. Brightwell, who always imparts an individuality to every creature he draws.

The Indian Earthquake (1934) Area

By Dr J. de Graaff Hunter, C.I.E.

MUCH attention has been recently focused on Bihar and Orissa Province as a result of the disastrous earthquake of January 15, and some facts about the condition of the earth's crust in that region have an enhanced interest It is, of course, no consolation to those who have suffered by the earthquake to be told that there were good reasons for it. These reasons have been in existence for a long time and yet, so far as I am aware, no earthquake of any magnitude has occurred there during the previous century.

The area roughly bounded on the north by the Himalayan foothills, on the south by the Ganges River and stretching from Meerut to beyond Darjeeling, between longitudes 78° and 89° is one of excessive underloading in the earth's crust (Fig 1) The average underloading of this area of about 100,000 square miles is on the average equivalent to a thickness of rock of more than 3,000 ft.; or, put otherwise, the deficiency of pressure in the crust is above 200 tons per square foot. This underloading arises from abnormally low densities in the crust It is in part accounted for by the low density of the alluvium of the Ganges valley; but unless this alluvium extends to a greater depth than most geologists would believe, the explanation is not wholly there

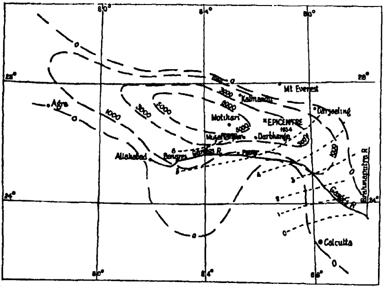

FIG 1 Sketch map showing main region of underload in Bengal, Bihar, etc and secular changes of level in Bengal

——— ——— ———, contours of underload in feet of equivalent thickness of rock, density 2 67

- - - - - - -, generalised contours of secular change of crustal level in feet per century

The presence of this region of underloading is revealed by measurements of the shape of the earth which have been accumulated during the past century by the Survey of India The area of underload is flanked both on the north and on the south by regions of overload; and the total overloading of the two outer regions is roughly equal to the underloading of the Ganges valley. Both the underload and overloads are reckoned from a state of isostatic compensation; so the northerly area of overload is not to be thought of as the weight of the Himalaya but something much smaller, as a considerable degree of compensation of the Himalaya is existent

These regions of great loading anomaly must cause very great stress-differences in the earth's crust which supports them The region of underload and the amount of underloading are very much of the order which has been estimated by Dr H Jeffreys to be sufficient to cause fracture in the lithosphere Now these stresses have no doubt been in existence for a long time In so far as the land level has been rising from sedimentation, known to have been in progress, some measure of relief has been afforded; but this has not been more than a small palliative. Meanwhile, evidence of another kind has recently come to light —again from the measurements of the Survey of India.

In 1858, spirit-levelling operations on a comprehensive scale were begun in India by General Walker. In 1862 work was carried out in Bengal, and since then measurements of this kind have accumulated. This accumulation gave rise to some embarrassment a few years ago, in that the newer lines of levelling gave results at variance with those of the older lines. After the whole system of lines had been carefully scrutinised, it was found that the apparent discrepancies would all be accounted for on the hypothesis that the land level had been rising so much each year, the rate of rise varying from place to place in a nearly uniform manner Thus along a line passing a little north of Benares and directed towards east-north-east an annual increase of elevation of 0·06 ft. was found; and other lines, approximately evenly spaced and roughly parallel to the first, showed rates of increase of 0 05, 0·04, 0 03, 0·02, 0 01, 0·00, the last being some fifty miles from Calcutta

It will be seen that this rising of the land is occurring in the south-east quadrant of this area of excessive underloading in the earth's crust. It is not necessarily confined to that quadrant. Evidence of change of level from spirit levelling results elsewhere has not yet been so carefully analysed, being not sufficiently complete None the less, revision levelling in the present century shows a persistent rise from Dhulia (lat. 20·9°, long. 74·7°) to Cawnpore (which also shows a small rise from Benares); and this, so far as it goes, confirms the Bengal results, which in turn are closely in sympathy with the underloading of which they are a natural consequence.

Before the earthquake occurred, the relevant facts accordingly were (*a*) that there was a large area of serious underloading, flanked by areas of overloading; (*b*) that in the part of this region where spirit levelled heights had been determined in sufficient detail at sufficient time intervals, the results indicated that the land has been rising steadily where the underload occurs, the rate of rise increasing as the centre of that region is approached.

A slow but continuous yielding of the crust has been in progress. When a material is stressed beyond its elastic limit, it yields in a non-elastic way and eventually fractures. In the present case, the earthquake gives evidence of fracture having occurred; and the floods which have followed the earthquake indicate the resulting rising of some portions of the area.

In the case of such a large area, fracture is not likely to extend throughout the entire region of stress, but it occurs at the position where the relation of stress to strength is most severe, and leads to a modification of the general stress distribution. There is no question of one earthquake of the magnitude of that which has recently occurred entirely relieving the stress differences. To do that an uplift amounting to thousands of feet would be necessary I have little doubt that spirit levelling will show that there has been some sudden rising of the land Were this of the order of tens of feet, it would immediately be made apparent by a wholesale change in the courses of the local rivers; and indeed, a recent report in the Press states that one of the most impressive features of the disaster has been such changes in river courses.

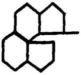
As stated earlier, the area from Meerut to Darjeeling is one of excessive underloading. A smaller amount of underload exists over a much larger area—a strip skirting the Himalaya from the Punjab to Bengal of width varying from 150 miles to twice that amount. We have so far discussed the eastern portion which provides the area of most acute underloading; but there is another region, roughly centred on Lahore (31 6°, 74 3°) where underloading of very considerable amount—about 2,000 ft of rock-equivalent—exists This region is not completely defined, as in the north-west it passes out of the area for which the necessary geodetic observations have been made It is just in this neighbourhood that the last serious Indian earthquake—Kangra (32°, 77°)—occurred in 1905. Eight years previously, in 1897, there was the Shillong earthquake, with epicentre at 26°, 91° Unfortunately, this is outside the area of full geodetic survey, and spirit levelling was not commenced in that region until 1900, so as yet we have no knowledge of what anomalies of loading exist there or of the secular changes of ground height

---

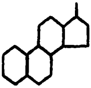
Recent Developments of Sterol Chemistry in Relation to Biological Problems

By JOHN PRYDE

ONCE again there has been demonstrated in striking fashion the impetus which organic chemistry gains from biology, and how a field of organic research, formerly of purely academic interest, enters on a fresh phase of development in virtue of a new correlation with biological problems The field in question is that of the sterols and the polycyclic aromatic hydrocarbons

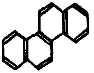


I

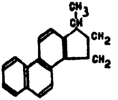


II

It is well known that the fundamental researches of Wieland, Windaus, Mauthner, Borsche, Diels and others on the sterols and bile acids received a new interest on the isolation of calciferol (vitamin D) from the products of irradiation of ergosterol, $C_{28}H_{44}O$, with which the vitamin is isomeric, and that our conceptions of the structure of these, and of other members of the cholane series to which they belong, have been re-oriented by the new formulæ advanced by Rosenheim and King[1]. The structures below show the old (I) and the now accepted representation (II) of the cholane nucleus. The new, and at the time somewhat revolutionary, formulæ conferred a great stimulus on the investigation of the whole series of compounds They are based upon evidence which cannot be detailed here, but some of the more salient of the recent observations can be summarised



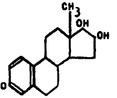
III



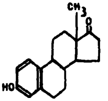
IV

Thus, on drastic dehydrogenation with palladium-charcoal or zinc, cholesterol and cholic acid yield the fully aromatic hydrocarbon chrysene (III)[2], whilst less drastic dehydrogenation of these compounds and of ergosterol using selenium yields an interesting hydrocarbon of the composition $C_{18}H_{16}$, first obtained by Diels and his associates[3]. For this latter the constitution IV was suggested by Rosenheim and King[4]. Kon[5] has very recently proved the correctness of this suggestion by a synthesis yielding the desired 3-methyl*cyclo*pentenophenanthrene. It is therefore clear that the formation of chrysene in the more drastic process is due to ring enlargement associated with the migration of a methyl group, and the revised cholane formula of Rosenheim and King becomes firmly established upon fact.

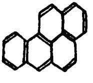
Secondly, the recent isolation and investigation of the female sex (œstrous-producing) hormone, mainly due to the efforts of Doisy in the United States, Marrian in Great Britain, and Butenandt in Germany, show that the hormone occurs in two forms—œstriol (V) and œstrone (VI), to adopt the nomenclature recently advanced in NATURE by workers in this field[6]. Evidence is available which amply establishes the close relationship of the œstrane and cholane series, which may be inferred from the isolation of the same 1 : 2-dimethylphenanthrene from œstriol and from ætiobilianic acid of the cholane series[7]. Mention may also be made of the isolation from œstrone, after dehydrogenation in the presence of zinc, of a hydrocarbon of the same C_{18} series as that obtained from the cholane compounds. To this hydrocarbon Butenandt has ascribed the composition $C_{18}H_{14}$, but in all probability the compound is impure chrysene $C_{18}H_{12}$.



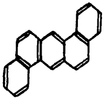
V



VI



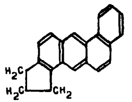
VII



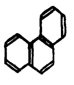
VIII

Thirdly, it has been known for many years that the tars and pitches resulting from the pyrogenic decomposition of coal and other organic products frequently possess carcinogenic properties. Much patient work in Great Britain, with which the names of Kennaway and Cook and their collaborators are associated, has culminated in the isolation[8] from a soft coal-tar pitch of a pure actively carcinogenic hydrocarbon, namely, 1 : 2-benzpyrene (VII). This, together with certain other but somewhat less active carcinogenic hydrocarbons [for example, 1 : 2 : 5 : 6-dibenzanthracene (VIII) and 5 : 6-*cyclo*penteno-1 : 2-benzanthracene (IX)][9] has been synthesised and the peculiar biological properties of these compounds have been amply proved.

It will therefore be realised that calciferol, œstrous-producing hormones, and carcinogenic hydrocarbons, all correlated with some phase of growth, all have the phenanthrene nucleus (X) in common. Lastly, the group of the cardiac-stimulating glucosides—strophanthin, digitoxin—yields aglucones in which the phenanthrene nucleus again occurs[10]. It may also be significant that some of the most powerful alkaloids, such as morphine, codeine, etc., of the opium group, the corydalis alkaloids and colchicine (meadow saffron) contain a phenanthrene nucleus. To this nucleus are added various cyclic and straight-chain substituents which confer on each group its characteristic biological activity.

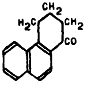


IX

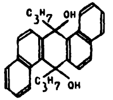


X

That these groups of compounds, of such apparently diversified physiological activities, should exhibit such fundamental constitutional similarities is sufficiently striking, but the story does not end here and indeed it would be bold to attempt to predict where it will end.



XI



XII

Mention has already been made in these columns[11] of the œstrogenic action of certain synthetic hydrocarbons and their derivatives—either themselves carcinogenic or closely related to carcinogenic compounds—and of the similar activity of some of the sterols and calciferol. Amongst the former are 1-keto-1 : 2 : 3 : 4-tetrahydrophenanthrene (XI) and 1 : 2 : 5 : 6-dibenz-9 : 10-di-*n*-propylanthraquinol (XII). In reference to the activity of the latter compound, it is of interest to note that a series of diols derived from 1 : 2 : 5 : 6-dibenzanthracene was investigated[12]. Of these the dimethyl, di-*n*-amyl, and di-*n*-hexyl compounds are inactive, whilst the intermediate diethyl, di-*n*-propyl and di-*n*-butyl compounds are all highly active, the propyl derivative showing the maximum activity The compounds mentioned above are the most active of those so far investigated, then follow in order of activity neoergosterol, 5 · 6-cyclopenteno-1 : 2-benzanthracene, 1 · 2-benzpyrene, calciferol and ergosterol That behaviour characteristic of a specific hormone should be shared by other compounds of related structure, some possessed of physiological activities of their own, provides a remarkable extension of our conceptions of biological specificity It suggests future developments of great interest in the chemistry and biology of the sterols and the polycyclic hydrocarbons

Obituary

PROF ERWIN BAUR

BY the sudden death of Prof Erwin Baur at the early age of fifty-eight years the science of genetics, and particularly plant breeding, has lost one of its foremost exponents. Having gone to Berlin to give an address at Harnack House on December 2 in commemoration of Correns, whose death was recorded only a year ago, he was suddenly struck down with angina pectoris and died within a few hours

Baur was born in 1875 at Ichenheim in Baden, the son of an apothecary He studied medicine in several German universities and was for one year assistant in the Botanical Institute at Kiel, receiving the degree of doctor of medicine in 1900 He served as ship's doctor on a voyage to Brazil, followed by a year of service in the navy He was afterwards assistant physician in the psychiatric clinic of the University of Keil and physician to an institute in Baden for the insane In 1903 he returned to botany and received the Ph D at Freiburg under Oltmanns, his thesis being on the development of the apothecia in lichens Apparently his first botanical paper was on the sex organs of the lichen *Collema* (*Ber deut bot Gesells*, 16, 1899), the figures from which have frequently been reproduced in textbooks Baur now migrated to Berlin as assistant in botany, where he became full professor and director of the Botanical Institute of the Königliche Landwirtschaftliche Hochschule in 1911

The rest of Baur's life was not only actively devoted to research in plant genetics and its applications (except for the last two years of the War, when he was transferred to Potsdam with his staff), but also in this period he founded and directed successively a new Institut fur Vererbungslehre in Berlin-Dahlem in 1922 and a still larger Kaiser Wilhelm Institut fur Zuchtungsforschung at Muncheberg, some distance from Berlin, in 1929

Erwin Baur was a man of tremendous energy and vigour, but overwork brought his life to an all too early end His well-known genetical investigations of *Antirrhinum* were begun about 1904, and already in 1910 he was growing some 30,000 antirrhinums a year. He also made the early studies of infectious chlorosis in Malvaceæ, *Ligustrum*, *Fraxinus* and other plants, and his investigations of graft hybrids and chimæras in *Pelargonium* and other plants were notable His "Einführung in die experimentelle Vererbungslehre", first published in 1911, has passed through eleven editions, and fulfilled somewhat the same functions in Germany that Bateson's well-known "Mendel's Principles of Heredity" did in England

In a series of classical researches, Baur first investigated the large number of colour factors and other mutational differences in the garden snapdragons Later his interest in the evolutionary aspects of the genus developed He collected and studied the wild species of *Antirrhinum* from Spain and other Mediterranean countries, finding throughout the genus that the specific differences behaved as Mendelian characters in crosses At the Muncheberg Laboratory the same genus was extensively used by Baur, Stubbe and other colleagues in the production of an extraordinary series of mutations in flower and leaf form by the use of X-rays, ultra-violet light, temperature shocks and a wide range of chemical substances These substances were forced into the leaves through the stomata by centrifuging seedlings which were inverted in tubes containing the solutions The plants were then set out and allowed to flower Baur's great knowledge of the wild forms of *Antirrhinum*, their distribution and genetics, will unfortunately be lost, as it had not been put in a form for publication

Baur's interests lay not only in the wider aspects of genetics but also in their application. This was exemplified in the Masters Lectures of the Royal Horticultural Society, which he gave in 1931 His general evolutionary outlook was that of Darwinian natural selection based on mutational variations, but the aims of the Muncheberg Institution were immediately economic Baur set about to produce a wheat suitable for light soils in Germany in place of rye, by crossing and selection on a huge scale By the testing of one and a half million lupins, plants were found in both the yellow and the blue species which were devoid of alkaloid and could be propagated as a forage field-crop. By similar large-scale selection a variety of *Melilotus alba* was obtained free from cumarin, and a tobacco free from nicotin. Efforts were being made to produce a grape which was resistant to *Phylloxera* and *Peronospora*, by extensive crossing with North American varieties and subsequent selection. Baur visited Peru and Bolivia, bringing back many native varieties of potato for use in plant breeding. Other large-scale crosses were made for the improvement of gooseberries, raspberries, blackberries and tomatoes.

In 1908, Baur founded and edited the *Zeitschrift fur induktive Abstammungs- und Vererbungslehre*, which has remained one of the standard journals for genetical researches and publishes a comprehensive classified bibliography of the world literature. He also founded the *Bibliotheca Genetica*, *Der Züchter*, and was joint editor of the *Zeitschrift fur Pflanzenzuchtung Gartenbauwissenschaft* and *Berichte uber die gesamte wissenschaftliche Biologie*. With Dr. M. Hartmann he had produced since 1928 the "Handbuch für Vererbungswissenschaft". He was thus instrumental in giving publication to a very large amount of important genetical work. Baur, with Fischer and Lenz, wrote the well-known "Menschliche Erblichkeitslehre und Rassenhygiene", which has seen several editions At the fifth International Congress of Genetics, held at Berlin in 1927, he was a leading spirit and gave the opening address as president of the local committee.

Prof Baur was an honorary member of many scientific societies and was elected a foreign member of the Linnean Society of London in 1933 An indefatigable worker, his results have been among the most fruitful in modern plant genetics R. RUGGLES GATES

PROF W. E. GIBBS

IT is with great regret that we record the death on January 18 of Prof. William Edward Gibbs, at the early age of forty-four years. Prof Gibbs was the Ramsay professor of chemical engineering at University College, London, having been appointed to that post on the resignation in 1928 of Prof E C Williams At the time of his appointment a large extension of the Department of Chemical Engineering had been planned, as the result of generous donations from various important British chemical firms, obtained through the energetic propaganda of his predecessor The extension was designed and carried out by Prof. Gibbs with conspicuous ability and success, and within a few years his genial personality, combined with his deep interest in research, his organising power and his practical knowledge of industrial methods and processes, had filled the much enlarged laboratory with a band of enthusiastic students drawn from many sources—young British university graduates, experienced men from various industries, and foreign students.

Prof. Gibbs was a graduate of the University of Liverpool, and obtained his first post as assistant chemist to the Straits Trading Company at Singapore. Having held this post for a few years, he returned to the University of Liverpool, and the present writer recollects the enthusiasm with which he attacked the problem of the electrochemical recovery of metallic tin from the waste smelter material which he had brought home with him. At Liverpool he was soon appointed lecturer in metallurgy, and he was also made investigator to the Corrosion Committee of the Institute of Metals.

During the War, Prof. Gibbs rendered valuable service to the country, holding successively the posts of chief examiner of the Aeronautical Inspection Department, and chief chemist to the Government Rolling Mills at Southampton At the conclusion of the War he was appointed chief chemist to the Salt Union, a post which he held until appointed professor at University College. During this period he acquired an extensive practical acquaintance with the technical methods and problems relating to evaporation and crystallisation

Prof. Gibbs was deeply interested in the properties and treatment of aerosols and aerogels, that is, disperse systems in gases, and wrote two excellent books, "Clouds and Smokes", and "The Dust Hazard in Industry", which are, so far as the present writer is aware, the first scientific expositions of these important subjects in book form in the English language He was also very much interested in problems relating to heat exchange, the flow of liquids and gases, the fractional distillation of liquid mixtures and the design of gas-scrubbers and rectifying columns. In these and other fields of chemical engineering he understood well how to combine the theoretical basis of design with the practical aspects of construction and operation, and he possessed the supreme gift of awakening and sustaining the intelligent interest of his students and securing their loyal and indeed affectionate co-operation.

Prof Gibbs was a man of high, unselfish and sterling character, combined with an endearing charm and simplicity of personality not often encountered in this world His untimely death is a severe loss, not only to his colleagues and students at University College, but also to the Institution of Chemical Engineers and the science and practice of chemical engineering throughout the world F. G D

DR. HERMANN CHRIST-SOCIN

BARELY three weeks before his hundredth birthday, and still fully in possession of his physical and mental faculties, Dr. Hermann Christ, the Nestor of European botanists, had the misfortune to slip on the polished floor of his study and to fracture his leg. Unfortunately, too, complications set in and he died on November 24 at his home in Riehen near Basle.

Though known throughout the world as a botanist, Dr. Christ was by profession a lawyer, for which career he prepared himself by studies in the Universities of Basle and Berlin. But, interested since his boyhood in natural history, Dr Christ took the opportunity while in Berlin to attend the excursions of Prof Alexander Braun, and his natural inclinations were greatly stimulated by his intercourse with that eminent botanist In his reminiscences, written on the occasion of his ninetieth birthday, Dr Christ relates with what great interest he read von Humboldt's works on the geographical distribution of plants, and on returning to Basle, he began to devote himself to this field of botany, publishing several short papers on special aspects of the flora of Switzerland, the substance of which he gathered together with further observations in his "Pflanzenleben der Schweiz" published in 1879

Dr Christ's interest in systematic botany was equally keen and his legal training seemed, as has been the case with other eminent botanists, to be of distinct help to him in sifting scientific evidence He occupied himself with the difficult genus *Rosa* on which he published his account of "Die Rosen der Schweiz" in 1873, and sixty years later, in his hundredth year, he published a further paper on this favourite subject of his dealing with the roses of the Canton Valais Other contributions to systematic botany dealt with the European conifers and with the European sedges, another difficult genus But it is with the group of ferns that Dr Christ's name will remain most closely associated The Ferns of Switzerland", "The Ferns of the World" and the "Geographical Distribution of Ferns" are three standard works which will always be consulted by pteridologists His industry as a botanist can be gauged from the fact that his botanical publications amount to more than three hundred and these were written during the time he could spare from his many professional activities as a lawyer, for he held an important legal post in connexion with the Swiss railways

Neither scientific nor professional preoccupations dimmed Dr Christ's humanitarian feelings, and on the occasion of the revelation of the Congo atrocities, he joined with Morel in organising the universal protest against the cruelties of the slave trade in Africa, and was one of the founders of the Swiss league for the protection of the natives in the Congo State

The influence of a man of such wide interests and insatiable activity carried on during an exceptionally long life has been felt far beyond the limits of his beloved town and country, and his untimely death, as one may call his passing away so near to the completion of his centenary anniversary, will be mourned by all his admirers, who will however keep him and his labours in grateful remembrance

---

WE regret to announce the following deaths

Dr Lilian J Clarke for several years head science mistress at James Allen's Girls' School, Dulwich, and member of many committees on the teaching of biology on February 12 aged sixty-eight years

Dr D W Freshfield, president of the Royal Geographical Society in 1914–17, of Section E (Geography) of the British Association in 1904, and of the Association of Geographical Teachers in 1897–1910, on February 9, aged eighty eight years

Dr Bernard Hollander, a well known authority on diseases of the nervous system, and author of books on psychology eugenics, and related subjects, on February 6, aged sixty nine years

Sir Lionel Jacob, K C S I , chief engineer and secretary to the Government of Burma in 1903–5 , inspector general of irrigation and secretary, Government of India (Public Works Department) in 1905–11 on February 9 aged eighty years

News and Views

Evolution of the Mind

WITH his customary lucidity, Prof Elliot Smith has presented, in the Royal Institution discourse which accompanies this issue of NATURE as a special supplement, an account of the present position of his researches in organic neurology in conjunction with the results of other workers, particularly Campion and Le Gros Clark The result is not only a notable step forwards towards an understanding of the complex temporo spatial relationships which from one point of view are designated the brain and its related mechanisms, and from another mental function, but it is also an effective counterblast to recent efforts prematurely to recrystallise Sir Henry Head's outstanding contribution to our understanding of sensory integration in forms of merely clinical application It is to be hoped that the danger to true progress in neurology resident in these efforts has been, if not averted, at all events withstood for the time being Poljak's demonstration that even in the simplest act of thought or skill the whole neopallium must participate reinforces the question, in respect of localisation'—the concern of clinicians—localisation of what ? The present contribution emphasises again the integrity of the brain as a whole as the effective instrument of a biological objective in action rather than in thought It may be said that with each advance in the evolutionary scale as well as in our understanding, the number of the neurological constituents of action is seen to increase

IT is not only that for the acquisition of the characteristic modes of the human *mind* a cognitive is added to an affective experience and to both is added a conative experience , but also for the development of the characteristic functions of the human *brain* a subtler progression eventuates, having little regard or none for these concepts of the schools In his most recent revelation of the stages of this progression, Prof Elliot Smith deals with those truly neurological 'bricks', the thalamus and the hypothalamus, the seats respectively of emotional formulation and effective expression, in the light of their special linkages with the cortex itself, facilitating a "cortico thalamic circulation" which finds functional expression in an enrichment of concepts by the gains of experience of failure or success in past action. While this broadening of the issues involved in what is now known of the fibre relationships of the cortical and thalamic organs is the outstanding feature of Prof Elliot Smith's lecture, a paragraph—all too brief—must not be overlooked which records the evident complexity of the neural machinery of the parts involved and proceeds to assert that "it becomes essential to look at the whole issue from a much broader point of view than the mere connexions of thalamus and cerebral cortex". The 'key' word of the sentence is 'connexions' and 'mere' is there to turn it vigorously Is it justifiable to hope that the self-sufficiency of the neurone is at last to be called in question and that the truly organic character of the brain may be substantiated 'in our time'? Is this not a case where the answer has long been prepared and only awaits the application of the question to reveal its fruitfulness?

Sir George Buchanan, C.B

By the retirement of Sir George Buchanan on February 18 from his post as senior medical officer of the Ministry of Health, an association with the public health of Great Britain of nearly forty years is terminated, for Sir George was appointed a medical inspector of the old Local Government Board in 1895 During this period he has accomplished much valuable work over the whole range of public health In early days he dealt with infectious disease outbreaks, questions of water supply and sewage disposal, housing problems and slum clearance During the five years 1906–11, he acted as chief inspector of foods, and afterwards was the chief assistant medical officer of the Local Government Board, becoming on the formation of the Ministry of Health its senior medical officer On the outbreak of War in 1914, Sir George was immediately attached to the Army Sanitary Committee and served on the eastern fronts at Gallipoli and in Macedonia and Mesopotamia, though little mention of the services he rendered there will be found in official records With the cessation of hostilities commenced his association with the League of Nations He had been a member of the Health Committee of the League from its foundation, and now became its vice-president, and he also became British representative of the Office International d'Hygiene Publique In 1919 he was a member of the Poland Typhus Commission instituted by the League of Red Cross Societies, was appointed president of the League of Nations Cancer Commission, and was a member of the League's mission for the public health reorganisation of Greece. In 1926, Sir George was appointed chief British delegate to the International Sanitary Conference. During the last twelve years he has assisted at numerous Government and official investigations This bare outline of Sir George Buchanan's activities during his official career suffices to show that he has played a part for which he has earned his country's gratitude

Dr. Thomas C. Porter

By the death of Dr Thomas Porter, for many years science master at Eton College and one of the founders of the (Public Schools) Science Masters' Association, on March 31, aged seventy-three years (Nature, 131, 496, April 8, 1933), science teaching in Great Britain suffered a severe loss An obituary article in the *Journal of the Chemical Society* of December 31 stresses Dr. Porter's influence as a teacher Though he was gifted with remarkable talent, he never allowed himself to specialise This wide range of interests was the source of inspiration which many of his pupils gained from him Porter was born at Bristol and was educated at the Grammar School, from which he gained a scholarship in natural science at Exeter College, Oxford, in 1878 In 1885 he was appointed at Eton, and there he taught for forty-eight years He was responsible for many improvements and extensions in the teaching of science at the College Dr Porter's own investigations covered a wide field. His most serious contribution was on the phenomenon of 'flicker', contributed to the *Proceedings of the Royal Society* in 1898, 1902 and 1912 He was the first to notice the non-homogeneity of X-rays (Nature, 54, 149, June 18, 1896) Papers on Newton's rings and the use of flames for enhancing the intensity of sound were published in the *Philosophical Magazine*

British Industries Fair

It has become almost a stereotyped phrase to say of each British Industries Fair that it is larger and more representative than any that have preceded it. The twentieth British Industries Fair to be held in London and Birmingham on February 19–March 2 maintains this tradition In the London Section the lighter trades and Empire exhibits will be found at Olympia, while the textiles and clothing and the furniture displays will be at the White City. The Birmingham Section at Castle Bromwich comprises hardware, house equipment, engineering and 'heavy' industries generally At Castle Bromwich there will also be an out-of-doors exhibition for the display and demonstration of agricultural implements, light railways, and quarrying and road-making plant. The trade groups which have shown the most marked growth, judged by the extent of their exhibits at the Fair, are furniture (the biggest section in the Fair) at the White City, electricity and building at Castle Bromwich, and the following groups at Olympia: Government of India, brush-ware and fancy goods; jewellery, pottery and glass-ware, sports goods; stationery, printing and office equipment, etc.; toys and games; chemicals and druggists' sundries It is interesting to note that the first British Industries Fair, which began as a War-time experiment in 1915, consisted of about 5 miles of stands at the Royal Agricultural Hall, Islington, whereas the stands of this twentieth Fair, in 1934, extend to about 32 miles or, say, fifteen times the length of Oxford Street. Incidentally, it may be noted that twenty-two Continental countries—another record—have given special travel concessions this year to encourage attendance at the Fair by their trades buyers. In these days of quotas and other forms of restrictions on international trade, it is very significant that twenty-two Continental countries should so appreciate the international importance of the British Industries Fair.

Sale of Contraceptives

ON February 13, Lord Dawson of Penn moved the second reading of the Contraceptives Bill. The provisions of the Bill were dealt with in a leading article in NATURE of February 10, p. 192. Lord Dawson said that birth control is now "part and parcel of our social fabric" and that he wished to identify himself with the view that the way to keep the sale and use of contraceptives on sound lines is "to remove the veil of doubt as to the honesty of contraception". Birth control is already accepted in practice, and if there were only wider acceptance of it in theory, the sale of contraceptives would go into normal channels. Meanwhile, he is of opinion that children and young persons require a certain amount of protection such as the bill would afford. Lord Dawson said that he is quite prepared to accept amendments provided that the principle of the bill is not undermined. The Bishop of London, while not agreeing with Lord Dawson, said he would support the Bill enthusiastically, giving as his reason the moral effect of the indiscriminate advertisement and sale of contraceptives. The Archbishop of Canterbury supported the Bill as being a serious attempt to check in some measure the growth of an evil which is poisoning the moral health, self-control and self-respect of the community. The motion for the rejection was negatived by 45 votes to 6.

Tree-Kangaroos

THE birth of a tree-kangaroo at the Gardens of the Zoological Society of London is an event well worth recording. Another was born at about this time last year. One would have supposed that the drastic change from the tropical forests of New Guinea and North Australia to a relatively small cage in London would have inhibited the reproductive activities. Even without this added interest, the presence of this strange creature in the Gardens is something more than welcome to all who are concerned with the problems presented by anomalous changes of habit and habitat in the animal kingdom. The typical kangaroo is, in itself, a sufficiently remarkable animal. For here we seem to have a convincing example of 'neo-Lamarckian' changes of form. Though how the initial stage of the leaping habit began we are scarcely likely to discover. It is not merely that the hind-legs and tail have grown inordinately large, but we have also to take into account the quite unusual nature of the reduction of the toes; for instead of disappearing on each side of a median axis, the reduction of the second and third toes has taken place on the inner side of the foot, where the claws only are visible in the living animal.

IT seems clear that the tree-kangaroo must have taken to an arboreal life after this specialisation for terrestrial leaping had taken place; though it is to be noted that, as in the wallabys, the hind-legs are shorter, and the fore-legs relatively larger than in the large ground dwellers of the tribe. Unfortunately, the opportunity of witnessing the actual birth of any of these animals occurs only on the rarest occasions, and it would seem that even then it is by no means easy to interpret what is seen. It used to be believed that the mother seized the infant at the moment of birth in her lips, and immediately transferred it to the teat in her pouch, to which it attached itself forthwith, and retained its hold continuously for some weeks while its further development took place. For the young, in the kangaroos, are, so to speak, prematurely born, with the limbs only slightly developed. A later account gives a very different version, embracing an astonishing degree of activity on the part of this almost embryonic little body. For it is said to make its way up the fur of the parent and into the pouch, and to find the teat unaided, a course of behaviour one would have deemed impossible.

Emigration Schemes in Australia

IN an article in NATURE of November 4 on population problems, reference was made to the failure of emigration for the time being. Commenting on the position, so far as Australia is concerned, Sir James Barrett, of Melbourne, in a letter to the Editor, states that the failure is not so disastrous in Australia as appears on the surface, despite the fact that, in Victoria alone, many millions of pounds will be lost on land settlement schemes. Few people realise that industrial farming requires for success scientific knowledge and training at least equal to that required in any learned profession. In his paper read before the World Population Conference in 1931 the late Prof. J. W. Gregory showed the importance of immigration to Australia in order that a population capable of making the utmost use of railways, etc., should be established in that country as quickly as possible. In Victoria more than £10,000,000 has been spent on irrigation works which, together with railways, were planned in accordance with a far-seeing land settlement policy. In addition, therefore, to the actual cost of land settlement schemes which the taxpayer, as Sir James Barrett says, is now forced to meet, there is this further heavy expenditure, much of which has been incurred directly for immigration and land settlement. Prof. Gregory also made some interesting references to the varying estimates that have from time to time been drawn up as to Australia's capacity for supporting a large population. These range very widely, from about 200,000,000 estimated by Admiral Sir Edmond Slade to about 10,000,000 and other similar low estimates made in Australia itself, for example, by F. C. Benham of the University of Sydney. Prof. Gregory's own estimate was more nearly 100,000,000.

Lord Bledisloe and the Promotion of Science

LORD BLEDISLOE, the Governor-General of New Zealand, has consistently encouraged scientific workers in the Dominion, and has promoted endeavours in all branches of science. As evidence of his keen scientific interest, during the visit of the Byrd Expedition II to Wellington on December 9, Lord Bledisloe promoted a happy scientific colloquium at Government House, when the visiting explorers were entertained along with the permanent scientific workers of the Dominion It is more than twenty years since so large a number of men belonging to different nationalities, whose researches are outstanding in different branches of science, have been gathered around one table in New Zealand The function allowed group discussions of all branches of the scientific work of the Expedition, which is probably provided with a larger scientific staff, and has a more extended scientific programme, than any expedition which has so far visited the antarctic Of outstanding interest is the work projected in cosmic ray determinations, and it is understood that the results on the trip from the United States have verified A H Compton's results in the variation with latitude of cosmic ray intensity The results of observations in the neighbourhood of the magnetic pole and on the polar plateau will be awaited with interest

The Byrd Antarctic Expedition

AMONG the interesting items in the programme of work of the Byrd Antarctic Expedition are the use of seismic reflection methods for the determinations of ice thickness and depth For this work, the expedition is well equipped with the latest types of apparatus Close attention will be devoted to upper air observations as forming a very considerable part of the extensive meteorological research programme which has been outlined The expedition is also proposing to take the fullest advantage of the opportunities afforded in this region for studying polar aurora. The biological and geological problems associated with Antarctica will also receive close study, and the scientific world should be considerably richer as the result of the labours of the staff of the Byrd Expedition II in the south polar regions

WE regret that news of the Expedition up to the end of January was not of a wholly reassuring nature. According to the *Times*, the larger of the two vessels of the expedition, *Jacob Ruppert*, was caught in the pack-ice and drifting in the Ross Sea. Apparently the ship had met with much difficulty on account of ice but had reached the proximity of the Ross Barrier by January 27; it began to discharge cargo on to the ice whence it was to be sledged by dogs and tractor to the base at Little America on the Bay of Whales. The following day, however, rifts appeared in the ice and several drums of petrol were saved with difficulty. The ship had to cast off, leaving a large party of men on the ice. The time now available for landing supplies is short since the ice is likely to freeze together at any time now, thus endangering the safety of the ship or at least its chance of getting away before the winter sets in.

Research and the Electrical Industry

THE thirteenth annual report of the British Electrical and Allied Industries Research Association for the year ended September 1933 gives an interesting résumé of the many problems on which it is engaged. In a foreword, Mr. C. C. Paterson, the chairman of the Council, says that the electrical industry has been built up by research, and by research only can it continue to prosper. This research must be made on a scale commensurate with its growth. Some of the researches described have a longer outlook than others, but none of the researches can be abandoned or even delayed without definite loss to the industry as a whole Much of the work done is in co-operation with other organisations. It is a pity that a number of large authorised electrical undertakings have not yet seen their way to become full subscribing members. The subscription assessment agreed to, at a recent conference, was £10 per £25,000 of revenue It is certainly not onerous. Research has often the effect of appreciably, and sometimes largely, reducing capital and working costs and hence non-subscribers are benefiting from work, the cost of which has been borne by others. The High Commissioners in London for the Dominions and Colonies have shown an active interest in the work of the Association, particularly the Indian Government Applications for membership have been received from several local State Governments and Public Works Departments We are glad to hear that the Association is taking an active part in locating the causes of radio interference. The solution of these urgent problems has involved sacrifices by the staff. They have been able to mobilise a squadron for field work and a mobile laboratory at short notice and are obtaining useful information

Industrial Health in Japan

IN Japan the pressure of a growing population has focused attention on the further development of industry, since in the next decade Japan has to find food and employment for nearly ten million more people than she does to-day. That the problem of industrial efficiency is being seriously tackled is evidenced in the annual report of the Director of the Japanese Institute of the Science of Labour at Kurasiki. This Institute was founded some years ago to undertake research into the physiological, psychological and environmental conditions affecting workers and their output. Research committees have recently been organised to investigate problems such as the rationalisation of labour, industrial fatigue, factory conditions and the appropriate qualifications to be desired of workers in every branch of Japanese industrial life. This latter investigation has already led to the establishment of standard norms for the mental and physical development of young Japanese workers aged 12–20 years. Occupational diseases

Supplement to NATURE

No 3355 FEBRUARY 17, 1934

Evolution of the Mind*

By PROF. G ELLIOT SMITH, F R S.

IT may be asked by what right an anatomist, whose proper business is concerned with very concrete subjects, presumes to discuss so elusive and immaterial a subject as the evolution of the mind even if it be admitted that the evolution of the chief organ of the mind comes within the proper scope of his field of work I am encouraged, however, to embark on this hazardous attempt by the considered judgment of Prof S Alexander, who once expressed the opinion "that we are forced to go beyond the mere correlation of the mental with [the] neural processes and to identify them"

The great physiologist who is most competent to express an opinion on this issue has recently impressed upon us the need for caution in touching it In the closing passage of his Rede Lecture on "The Brain and Its Mechanism", delivered in Cambridge on December 5, 1933, Sir Charles Sherrington used these words "I reflect with apprehension that a great subject can revenge itself shrewdly for being too hastily touched To the question of the relation between brain and mind the answer given by a physiologist sixty years ago was 'ignorabimus' But to-day less than yesterday do we think the definite limits of exploration yet attained The problem I have so grossly touched has one virtue at least, it will long offer to those who pursue it the comfort that to journey is better than to arrive, but that comfort assumes arrival Some of us—perhaps because we are too old—or is it too young ?—think there may be arrival at last " These opinions are even more appropriate to those who lack Sir Charles Sherrington's immense competence

Hence I seize upon a confession made by Sir Charles elsewhere in his Rede Lecture

"What right have we to conjoin mental experience with physiological ? No scientific right', only the right of what Keats, with that superlative Shakespearean gift of his, dubbed 'busy common sense' The right which practical life, naïve and shrewd, often exercises "

If scientific proof, however, is demanded, surely Sir Henry Head's investigation of sensation and the cerebral cortex supplies it by demonstrating in wounded soldiers the concern of the cortex with psychical functions—the dependence of mind on brain ("Studies in Neurology", 1920) Prof Shaw Bolton, by comparative and clinico-pathological researches, has demonstrated the dependence of mind on the supragranular layer of the cerebral cortex

With these assurances the mere biologist, while discussing strictly biological issues, can direct attention to certain psychological implications of anatomical facts and comment also on their neurological aspects for the interpretation of the mind and its working In previous lectures at the Royal Institution I have discussed the significance of the heightened powers of vision in man's ancestors, which conferred upon them the ability to see the world in which they were living and appreciate something of what was happening in it, as well as to guide their hands to acquire skill, by the practice of which fresh knowledge and understanding were obtained

SIGNIFICANCE OF VISUAL GUIDANCE

We know enough of the comparative anatomy and palæontology of the Primates to select a series of animals that can be taken to represent approximately the stages through which man's ancestors passed in their evolution towards man's estate, and by examining the connexions of the optic tracts in the brain, arrive at an understanding of what is involved in the acquisition of higher powers of visual discrimination (Fig 1)

In this series of diagrams, it will be observed that at first the areas for touch, vision and hearing come into contact with one another but that eventually an area marked *P* (parietal association area) develops between them to provide a more efficient place of blending of the impulses from these three senses At the same time there emerges from the front end of the brain a prefrontal area (*F*) which is essentially an outgrowth of the motor territory and an instrument whereby the activities of the whole cortex can in some way be concentrated on the process of learning to give motor expression to the total activities of the hemisphere Certain poisons which exert a destructive influence on the supragranular layer of this part of the cortex lead to very significant mental results, such as are displayed in general paralysis of the insane, characterised at first by grandiose delusions and afterwards by a failure of the mental process altogether, profound dementia The discussion of this evidence by Dr J Shaw Bolton ("The Brain in Health and Disease", 1914) affords another precise demonstration of the dependence of the mind upon particular parts of the brain

---

* Friday evening discourse delivered at the Royal Institution on Jan 19

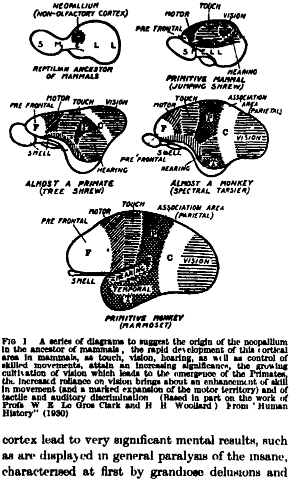

FIG 1 A series of diagrams to suggest the origin of the neopallium in the ancestor of mammals, the rapid development of this cortical area in mammals, as touch, vision, hearing, as well as control of skilled movements, attain an increasing significance, the growing cultivation of vision which leads to the emergence of the Primates, the increased reliance on vision brings about an enhancement of skill in movement (and a marked expansion of the motor territory) and of tactile and auditory discrimination (Based in part on the work of Profs W E Le Gros Clark and H H Woollard) From "Human History" (1930)

This is an example of the means whereby comparative anatomy can throw light upon the process of mental evolution, the structural changes in the eyes and brain which make possible not only the refinement of visual discrimination, but also the increasing participation of visual perception in the conscious life and in the guidance of the instruments (such as the hands) of muscular skill The latter consideration is one of fundamental importance For the study of the evolution of the nervous system impresses upon us the fact that one of its essential purposes is to make possible quicker, more complex and more purposive responses to changes in the animal's environment or the conditions in its own body

It is a matter of real importance, therefore, that every advance in the powers of sensory perception and discrimination should be brought into relationship with this essential biological need of finding expression in action Each of the major advances in vertebrate evolution is obviously correlated with differences in locomotion and muscular aptitude When an amphibian emerged from a fish-like ancestor, the most obtrusive change was the substitution for swimming as a means of locomotion, the use of the newly-created 'gadgets' which are represented by the limbs of a tetrapod land-living animal The attainment of greater competence and agility in the control of the amphibian's four legs led to the emergence of reptiles, from which in course of time birds and mammals were evolved, the former by high specialisation of the forelimbs by flight, and the latter by the acquisition of a cerebral instrument, the neopallium, which conferred the ability to attain unlimited powers of acquiring skill and to profit from experience The highest powers of skill were made possible by the evolution of greater powers of visual guidance

It is an obvious truism that man's mental superiority is largely the outcome of the perfection of the co-operation of hand and eye in the attainment of manipulative skill and dexterity In the use of the hands for the expression of skill, the skin of the fingers acquires heightened powers of tactile discrimination, and thus becomes the special organ of the sense of touch and an instrument of perceptual knowledge second only to the eyes in significance

The researches of Sir Henry Head and his collaborators have given us a new understanding of what is involved in tactile discrimination The great sensory pathways in the spinal cord and brain-stem lead up to the thalamus in the fore-brain, where they end in its ventral nucleus, the nerve cells of which transmit impulses in two directions—one to the cerebral cortex and the other to what Sir Henry Head calls the essential organ of the thalamus The former is regarded by him as the mechanism for sensory discrimination, and the latter as the instrument for awareness to sensation and the appreciation of its affective qualities, its pleasantness or unpleasantness

HYPOTHESIS OF A THALAMO-CORTICAL CIRCULATION

In the *British Journal of Medical Psychology* in 1932, Mr George G Campion discussed the psychological implications of Head's clinical results Emphasising the impossibility of separating from perception the affective factor, which is continually at work in our thought-processes, Mr. Campion gave expression to the view that the biological purpose of giving a meaning to experience is the essence of the comprehension of the nature of sensation Mr Campion has emphasised the further fact that the concept—the ultimate constituent element of what are called our cognitive dispositions—is not fixed and unchangeable, but is "a living plastic mental symbol subject to a process of organic growth, and that its growth is due to an affective factor which is constantly at work determining the selection of new sense data from the perpetual flux, interpenetrating the conceptual contents of our minds, and integrating all these various and varying constituents into the slowly maturing dispositions which constitute organised knowledge The affective factor involved in this process has been variously called 'libido', 'love', 'interest', 'feeling', 'desire', 'liking', etc "

Mr Campion further maintains that there is a continuous stream of neural impulses from the thalamus to the cortex and from the cortex to the thalamus, which keeps alive this living process of mental growth—the enrichment of the concept as the result of personal experience, the success or failure of the attempts to do things

Developing this idea, Mr. Campion directs attention to the various parts of the cortex linked in an incredibly complicated way by association fibres and cortical association areas. The necessary implication of his hypothesis of the thalamo-cortical circulation of neural impulses (by means of the various thalamo-cortical and cortico-thalamic tracts of fibres), involves functional connexions of the various parts of the thalamus with one another by intercommunicating fibres. He predicts that as "the cortical association areas may be assumed to have a counterpart also in the thalami, it will be for neurologists to say whether these hypothetical association areas lie in and constitute a chief part of what Head has called the essential thalamic organs "

Since this prediction was made, Prof Le Gros Clark, in the course of studies (*Brain*, vol 55) in the comparative anatomy and physiology of the thalamus, has directed attention to the fact that such elements are actually found in the thalamus of the higher mammalia There are cell masses (lateral nucleus (Fig 3)) deriving their impulses from the main sensory part (ventral nucleus) of the thalamus, which merge sensory impulses of different kinds and establish direct connexions with those association areas of the cortex which link together the cortical sensory areas This remarkable confirmation of Mr Campion's hypothesis adds force to the argument that the mechanism of correlation in the thalamus is far more complicated than has hitherto been supposed, and represents what, following the lead of Sir Henry Head, one may suppose to be a mechanism for the integration of affective processes in the same way as the cortex effects the integration of the discriminative or cognitive aspects of experience

In the process of acquiring knowledge and building up these vital mental elements, the concepts, to which reference has already been made, it is obvious that there must be a circulation of nervous impulses such as Mr Campion assumes to maintain the cohesion and the integrity of the vital processes of thought This circulation of impulses must be even more complicated than he has assumed, because the hypothalamus undoubtedly enters into the process and influences the activities both of the thalamus and the cortex, adding as its quota the visceral element which confers upon experience an emotional factor which is something more than the affective interest the thalamus is able to provide Intimately intertwined with the whole of this complicated system —hypothalamus, thalamus and the sensory and association areas of the cortex—we have the complex mechanism for giving expression to their combined activities in actions which represent the biological purpose of the whole process. The powerful instrument of thought represented by speech affords an admirable illustration of the intimate correlation of muscular skill with cognitive aptitude to provide the essential currency of mind.

Almost every part of the cerebral cortex is intimately connected directly and indirectly with mechanisms in the central nervous system which are concerned with muscular activities, either those which directly effect movements, or on a vastly greater scale those which prepare and co-ordinate the state of the muscles of the whole body in readiness for prompt and efficient action. More than two-thirds of the fibres that leave the hemisphere have as their immediate purpose the establishment of connexions with the cerebellum, and as their function, the rapid distribution of the muscular tone of the body in readiness for such skilled action as lies at the root of the brain's efficiency. The circulation of the thalamic and cortical currents maintains this constant state of readiness and is a vital and essential part of consciousness and mind.

The building up in the brain of concepts is dependent not merely on affective and cognitive experience based upon afferent impulses from the sense organs, but is also brought about as the result of muscular activity, the doing things with the hands, the gradual perfecting of the movements, the results of the success or failure of such efforts, and the afferent impulses which pour into the brain from the joints, the muscles and the skin areas to record the success or failure of particular muscular activities. It is largely by doing things that experience is built up. It is important therefore to recognise the very large part which such conative activities play in the building up of concepts. They are due not merely to the interaction of the affective and cognitive dispositions, but also to the dynamic factor which is conferred upon these processes by attempting to express in action the result of the discriminative activities of the cortex.

THE NEOPALLIUM AS THE ESSENTIAL MENTAL INSTRUMENT

More than thirty years ago, I directed attention to the fact (*J. Anat. and Physiol.*, p. 431, 1901) that with the evolution of mammals a new cortical instrument, which I called the neopallium, came into existence, and with its expansion provoked the vastest revolution that ever occurred in the cerebral structure. It came into being to form a receptive organ for fibres coming from the thalamus, whereby touch, vision, hearing and taste—in fact all the non-olfactory senses—secured representation in the cerebral cortex. To express this fact, Prof. Winkler, of Utrecht, calls the neopallium the thalamocortex.

In its earliest form the neopallium consists of a tiny area far forward in the hemisphere, where tactile impulses from the lips and tongue are brought into relationship with olfactory and gustatory impulses, and this area afterwards acquires the ability to control the movements of the lips and tongue. As the neopallium grows it establishes similar relations to the rest of the body and increases the range of its receptive powers not merely to the skin of the whole body, but also to the eyes and ears, and it establishes direct connexions with all the motor nuclei in the central nervous system. The neopallium not only gives the senses other than smell representation in the dominant part of the brain and a part in the control of behaviour, but it also provides a continuous territory in which co-operation between these various sensory influences can be established and their conjoint effects be brought to bear upon the mechanisms that control motor activities.

It is often supposed that there are in the cerebral cortex long association bundles to establish connexions between distant parts of the cerebral cortex. There has recently been published an important memoir by Dr. Stephan Poljak, a Jugoslav neurologist who began the research in question in my laboratory eight years ago, which disproves the existence of such long connexions. An impulse from one cortical area can only reach and influence distant areas by travelling through the cortex itself. The act of correlation involves the whole cortex. Even in the simplest act of thought or skill, the whole neopallium participates. The manifold currents which circulate throughout the brain in the process of regulating muscular activities represent the means of integrating the cognitive, affective and curative activities in thought.

Not only the neopallium but also the brain as a whole adds its quota to the action—in particular the great mass of nervous matter at the threshold of the cerebral hemisphere known as the thalamus. It contributes the affective element, which is the interest, the stimulative of the whole complex process, to which it gives coherence. The cortex not only preserves the records of previous experience which provide the means for comparing present experiences with past happenings, but it also adds the spatial quality to sensation and the means of judging degrees of stimulation, and the afferent impulses which pour into the brain from the joints, the muscles and the skin areas, to record the success or failure of particular muscular activities It is by doing things that experience is built up. It is important therefore to recognise the very large part which such conative activities play in the building up of concepts They are due not merely to the interaction of the affective and cognitive dispositions, but also to the dynamic factor which is conferred upon these processes by attempting to express in action the result of the discriminative activities of the cortex

For some years I have been attempting to demonstrate how vast a part the cultivation of visual discrimination has played, not simply in making it possible for human beings to see the world in which they live and appreciate some of the activities which are revealed to them by their eyes, but even more in contributing to conscious control of behaviour.

The earliest type of cerebral cortex necessarily has to perform both affective and cognitive functions It enables its possessor to appreciate the attractiveness or unattractiveness of a particular scent, and to experience an interest in addition to the cognitive recognition of it

The cortex, at first, however, exercises no immediate direction over the motor activities of the animal beyond provoking them and providing the initiative to action This it accomplishes by transmitting to a mass of grey matter in its base (the corpus striatum) impulses which indirectly throw other parts of the brain and spinal cord into action to direct the movements that it starts It is the impulses from the eyes, skin and "ears" (as yet organs not of hearing, but of recording movements in the water) which consciously direct the animal's movements, while its posture and equilibrium are being maintained by the automatic mechanism of the membranous labyrinth

The tracts in the brain which convey the impulses from skin, eyes and ears are mainly concerned with transmitting to the various motor nuclei impulses that unconsciously influence and direct reflex movements, but they all send some of their impulses to a mass of grey matter in the forebrain, which lies immediately behind the striatum, to which it is intimately linked by many nerve fibres This is the thalamus (Fig 2) It confers upon all the non-olefactory sensory impulses an affective quality which gives them a meaning and an influence in modifying behaviour In other words, the effects of this sensory experience, when transmitted to the striatum, are to alter the animal's reactions to smell

EMOTIONAL FACTOR IN MIND

The activities of the striatum, when stimulated by the cerebral hemispheres and the thalamus, are expressed in impulses which proceed from it to the hypothalamus, a mass of grey matter lying beneath the thalamus This surprising arrangement seems to confer upon the hypothalamus the decisive influence in translating into behaviour the initiative to action which lies in the cerebral cortex The hypothalamus is the part of the brain which controls, by means of the sympathetic and parasympathetic systems, the most vital activities of the body itself, its visceral functions, its growth and metabolism, and even such appetites as those of sex It is the essential instrument of emotional expression

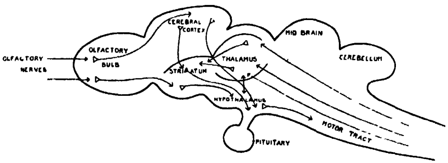

FIG 2 Diagram of the primitive vertebrate brain to suggest the hypothalamic, thalamic, striatal and cortical connexions

As the springs of action are profoundly influenced by hunger, thirst, sexual desire and other appetites and cravings, it is perhaps not surprising that in the most primitive vertebrates the instrument of the animal's vegetative needs should play a crucial part in shaping its conduct To this part of the brain, impulses proceed from the olfactory tracts so as directly to control the activities of the alimentary and genital systems in anticipation of the realisation of the satisfaction of the respective appetites

The study of the primitive brain impresses upon us the intimacy of the integration of the functions concerned with affective and discriminative knowledge and the translation of such information into appropriate action.

The higher type of brain distinctive of mammals, which opens up the possibility of the attainment of real conceptual knowledge and its biological application in increasingly complex acts of skill and thought, is distinguished by the growth of the thalamus and the transmission from it to the cerebral cortex of fibres in increasing numbers (Fig 3)

The recent progress in our knowledge of the structure and connexions of the thalamus and hypothalamus with the cerebral cortex, the hypothalamus and the sympathetic and visceral tracts of the organism had made it possible to carry Mr Campion's suggestions a stage further than he himself has done That this is possible is in large measure due to the illuminating researches of Prof W E Le Gros Clark The intensive studies which have recently been made by scores of investigators on the structure and connexions of the hypothalamus enable us to broaden the issues and consider the part played by these portions of the brain, which control the growth and metabolism of the body, and in particular visceral function, and how they are related to the thalamus and the cerebral cortex and provide the instrument for determining the emotional colour of experience and of regulating the manifestations of the appetites

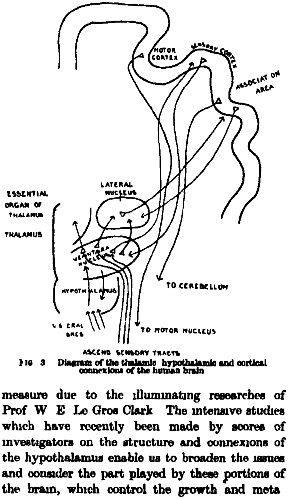

FIG 3 Diagram of the thalamic hypothalamic and cortical connexions of the human brain

If Mr Campion's views are correct, that the study of this neural machinery is essential for the understanding and interpretation of thought and behaviour, its structure and functions might be expected to be of great complexity Hence it becomes essential to look at the whole issue from a much broader point of view than the mere connexions of thalamus and cerebral cortex

IMPORTANCE OF SMELL IN THE PRIMITIVE VERTEBRATE

In the brain of the most primitive vertebrate, the structural pattern is determined by the fact that smell is the dominant sense The cerebral cortex is essentially a receptive instrument for impressions of smell, and the mechanism whereby consciousness of smell can influence the behaviour of the animal When a primitive vertebrate such as a dogfish scents attractive food and pursues it, the culmination of the pursuit is represented by the seizure of the food and the appreciation of its taste This is nearly akin to the initial olfactory experience which started the pursuit and dominated it, so that all the incidents of the pursuit become integrated into one experience, which is thus given coherence and meaning Thus is initiated the ability to anticipate the result of a given course of action, and to recall in memory the connexion between the various incidents

One must assume, therefore, that the primitive cortex is concerned not merely with the awareness of smell and the ability to discriminate between different kinds of smells, but also that it is concerned with the affective side of olfactory experience, with the attractiveness or repulsiveness of any scent and the influence of such affective experience in determining the nature of the response an individual odour can evoke The cerebral cortex in such a primitive animal is incapable of directing movements, seeing that the sense of smell is utterly devoid of any spatial quality When an animal scents an attractive food, it acquires from the sense of smell no idea as to the position in space of the object which provides the stimulus It is merely stirred into action, and other neural mechanisms are responsible for controlling and directing the resulting activities The cerebral cortex, so to speak, is the mere trigger which releases the activity of the brain and provokes and directs the movements

The part of the cerebral hemisphere which translates these stimuli into action is the corpus striatum, and the striatum is connected with the thalamus, which receives from the body, that is through the skin, the eyes and the ears as well as the muscles and joints, impulses which modify and direct movements which result when the animal is thrown into action. The thalamus transmits the effects of these stimuli to the striatum and so modifies the motor activities. In the case of organs such as the eyes, the primary functions were concerned not merely with the awareness of illumination, but also of movements in the outside world, or rather movements of objects in the outside world in reference in its own body The eyes have associated with them, in the brain, a complicated mechanism which enables them automatically to direct the movements of the body in relationship to events in the outside world. But quite apart from this, the eyes transmit to a part of the thalamus (the lateral geniculate body) impulses which are concerned with the awareness of the stimulus of light, and which influence these bodies and through them the thalamus as a whole, which in turn affects the functions of the striatum and the movements of the animal

In the primitive vertebrate one must assume that the thalamus acts as an affective organ of all senses other than smell, and represents the instrument whereby the organism is pleasantly or unpleasantly affected by sensory experience, and that the cerebral cortex performs the analogous but more dominating aspect of the same function in relationship with smell. The dominant part of the cerebral cortex in the most primitive vertebrate is the hippocampal formation, and if one assumes the supreme function of the cortex is to determine the behaviour of the animal, it is perhaps justifiable to assume that the purpose of the primitive hippocampus is to make possible the adequate association of the affective qualities of smell and to translate them into action by playing a dominant part in determining the animal's behaviour.

It is perhaps not without significance in this connexion that the efferent fibres from the hippocampal formation, after passing out of the cerebral hemisphere, terminate in the hypothalamus, that part of the brain which controls the visceral system (sympathetic and para-sympathetic) and thereby regulates the activity of the viscera It is, in fact, that part of the brain which is intimately related to the functions of the appetites Nor is it surprising that the particular part of the hypothalamus in which the hippocampal fibres terminate should be linked up with the thalamus, so as to provide a neural circuit in which the total affective qualities of all the senses are brought into relationship in such a way that they can influence through the striatum the motor responses of the body

The researches of Prof. Le Gros Clark have established the fact that the thalamus contains three kinds of cell groups (Fig. 2). Those forming the ultimate termini of certain of the sensory pathways, which according to Sir Henry Head form the essential organ of the thalamus, are the instrument whereby we become aware of sensory experience and appreciate its affective qualities. Secondly, there is a group of cells (ventral nucleus) which receives the great sensory paths coming up from the other parts of the brain and the spinal cord, and transmits the impulses either to the corpus striatum or in mammals to the neopallium In the third place, there is a group of nuclei in the thalamus which become well developed only in the higher mammals They do not receive afferent impulses directly, but only from the intermediation of the ventral nucleus The highest type of thalamic cells, known as the lateral nucleus (Fig 3), establishes connexions with the parietal area of the neopallium, which intervenes between the sensory cortical areas for touch, vision and hearing (*P*, Fig. 1), and presumably confers upon this area the ability to provide sensory experience with spatial and discriminative qualities All three categories of thalamic elements are intimately joined together by numerous fibre tracts so as to form a closely integrated functional whole the proper working of which is essential for cortical functions

INTEGRATION OF THE DISPOSITIONS OF THE MIND

The common practice of psychologists of segregating the three dispositions of the mind, cognitive, affective and conative, and attempting to study them as isolated units, is devoid of justification. All three are indissolubly united in the working of the mind. To give them cohesion it is necessary to assume the existence of a circulation of nervous impulses from the thalamus to the cortex and to the widespread and complex mechanisms concerned with muscular activities

In the growth of a concept conation plays a fundamental part. Man learns from experimentation By the exercise of his manual dexterity he acquires knowledge of the properties of things, the nature of forces, and the means for interpreting (and in some measure understanding) the world in which he lives. The surprisingly large part of the cerebral cortex that is concerned with the regulation of muscular functions and the multitude of its fibre-connexions with the cerebellum affords an impressive testimony of the vast significance of action in mind-making and emphasises what Prof T. H Pear has well called "the intellectual respectability of muscular skill" It is a truism that we learn by doing In man, thought is a prerequisite for action, and action a corrective of thought The biological justification for the evolution of the high degree of visual discrimination, whereby man knows the world and the society in which he lives, is the motor efficiency it makes possible

The most significant factor in the evolution of the mind was effected when the direction of movements was transferred from the midbrain to the neopallium (see NATURE, 125, p 820, 1930) and from being an unconscious automatism became a consciously directed process For the neopallium not only established a direct control over the motor nuclei of the whole central nervous system, but it also became linked up with all the complicated machinery in other parts of the brain which are concerned with muscular activities

This concentration of control in the neopallium implies a circulation of nervous impulses throughout the brain to effect cohesion between the living instruments of the conative dispositions with those of the affective (thalamus) and cognitive (neopallium) dispositions of the mind A circulation such as Mr Campion postulates is essential to the working of the mind. This circulation in turn involves the hypothalamus, which presumably confers the emotional tone that plays a part in all mental and muscular activity, in particular in artistic expression and the self-knowledge which is one of the most distinctive qualities of man and his thinking

Anthropological investigations, the results of which I have summarised in chaps v and vi of my "Human History" (1930), suggest that in primitive man there is an innate goodness and truthfulness, the awareness of which we call conscience Those qualities of the mind are responsible for character and personality. The terrible experiments which the incidence of diseases such as sleepy sickness (encephalitis lethargica) provides, has shown that these amiable qualities can be destroyed by minute injuries of certain parts of the brain in or in the neighbourhood of the hypothalamus We must suppose that these parts of the brain are responsible for the maintenance of the innate goodness of human nature, the goodwill of normal man, seeing that their destruction causes so profound an alteration of character Mr Campion's hypothesis of a widespread circulation of nervous impulses provides an explanation of how these various dispositions of the mind and character may be integrated into the living human personality

Before I close this discourse, I must express my gratitude to Mr George Campion for his stimulating suggestions and to Prof J S B Stopford, of Manchester, for help in giving them neurological expression

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO, LTD, ST ALBANS

have also been studied, and in this connexion special attention has been paid to skin diseases among typical Japanese manual workers such as stevedores, octopus fishers, plasterers, carpenters and blacksmiths Every effort is made by the Institute to maintain close contacts with industry, and its *Journal* is now to be issued bi-monthly instead of quarterly, so that the results of its researches may be available as soon as possible Recently also the Japanese Association of Industrial Hygiene—an organisation which is closely connected with the Institute—has considerably increased its activities

The Rockefeller Foundation

THE Rockefeller Foundation's report for 1932 is a tale of activities which, in extent, variety and momentum, are probably unmatched by those of any other agency for world betterment Of the aggregate disbursements during the year, amounting to nearly 14 million dollars, about one fifth was for public health work carried on in almost every country of the globe The report of the director of the international health division covers some two hundred pages and includes a retrospect of the past ten years This is followed by reports of the directors for the medical sciences, natural sciences, social sciences and humanities, and in each case the recital of events of the year is elucidated by reference to previous years' achievements The chapter on the social sciences is of special interest at the present time, showing, as it does, that the framers of President Roosevelt's administration's schemes for national recovery, however handicapped by lack of precedents, were at any rate in a position to draw upon the results of elaborate academic research, to the financing of which the Foundation has for some years made very substantial grants In addition to grants to various institutions for current expenses, including in 1932 grants amounting to 450 000 dollars to the Social Science Research Council in New York City, the Foundation has recently promoted research in specific fields recognised as of specially vital importance, namely, economic planning and control, international relations, and community organisation In 1932, substantial grants were made for research in such subjects as industrial hazards, history of prices, unemployment, employment exchanges, the gold standard, cyclical fluctuations and employment stabilisation

Progress of Agricultural Research in Great Britain

THE collected reports on the work done during the year 1931–32 at agricultural research institutes in the United Kingdom which receive State grants has just been published The volume contains in addition reports on special agricultural investigations for which funds have been allotted Among these the following may be cited investigations on improved grassland management at the Welsh Plant Breeding Station, Aberystwyth, and the University of Bristol, seed potato production at the University College of North Wales, Bangor, land reclamation with *Spartina townsendii* (rice grass) by the Essex County Council, grey squirrel problems at the Department of Zoology, University of Oxford, and the efficacy of chlorates as weed killers at the North of Scotland College of Agriculture A list of papers published by each research institute or centre and the names and addresses of the directors or persons in charge of the investigations are supplied, so that further information on special points can be obtained if desired. The report can be obtained from H M Stationery Office or through any bookseller, price 6s net

THE Royal Agricultural Society, 16, Bedford Square, W C 1, has published the eighth of its annual summaries of the research work carried out in the leading branches of agriculture In previous years the publication has been issued in book form, free on application to members of the Society and available at a nominal charge to the general public In the present year, and for the future, "The Farmer's Guide to Agricultural Research" will form part of the Society's *Journal* and will, therefore, automatically be received by every member A limited number of copies however, are still being bound separately for distribution to the Press and to agricultural education and research centres The survey of scientific work which it provides is not limited to research conducted in the British Isles, but also includes references to results obtained in any part of the world which may have a bearing upon the problems of British agriculture The character of the volume is similar to that of the previous year (1931), except that the section on farm crops which was then omitted has been reintroduced The other sections, namely dairy farming, diseases of animals, farm economics, the breeding of livestock, farm implements and machinery, pests and parasites, and soils and manures remain as before A few copies of previous issues for the years 1925–1931 are stated to be still available

A Natural History Society in Northern England

WHILE interest in museums appears to be growing, many societies devoted to natural history find it difficult to retain the membership of former years. The Northumberland, Durham and Newcastle-upon-Tyne Society is fortunate in having raised its membership, by a small addition, to 613, but even so the cost of running the Hancock Museum is mainly responsible for a raiding of the Maintenance Appeal Fund to the extent of £245, so that the Fund is on the verge of extinction The Museum does good work, and under the guidance of T Russell Goddard and many helpers, is alive to the need for interesting the public by wild-flower exhibits, seasonal exhibitions of *Lepidoptera*, an observation hive, lectures and the like Unless further support is forthcoming, it would appear from the financial statement that the activities of the Museum run the danger of curtailment

First Aid in the Laboratory

WE have received a copy of a pamphlet entitled "Safeguards in the Laboratory", together with a notice suitable for exhibition in the laboratory, both of which are obtainable, price 6d post free, from

Canon Kirkland, The King's School, Ely The pamphlet contains a number of very useful hints for first aid in the laboratory, which have been compiled by the Science Masters' Association and the Association of Women Science Teachers, and it should be very useful in the school laboratory. It should be noted, however, that the administration of an emetic, particularly salt solution, as stated, is not advisable in the case of mercuric chloride without first giving immediately white of egg. the section on poisons is not sufficiently detailed to be of much real value. The statement that "the naphtha used for storing sodium should be of the native rock-oil variety" is rather obscure

Ross Institute and Hospital for Tropical Diseases

Reports of the annual general and extraordinary general meetings of the Ross Institute and Hospital for Tropical Diseases, held on November 27, have now been released for circulation. At the eighth ordinary general meeting, the chairman, Sir Charles McLeod, surveyed the work of the Institute during the year, and the Council and Executive Committee were re-elected. At the extraordinary meeting, it was resolved to approve and confirm two agreements made between the Ross Institute, of the one part, and the London School of Hygiene and Tropical Medicine, and the Seamens' Hospital Society, respectively, of the other part, whereby the Ross Institute is amalgamated with the London School of Hygiene and Tropical Medicine, and the Ross Hospital is incorporated in the Seamens' Hospital Society by the establishment of a "Ross Ward" in their Hospital for Tropical Diseases The Court and Senate of the University of London have expressed their satisfaction respecting the arrangement with the School of Hygiene The Ross Institute thus comes to an end, but the name of Ross will still be perpetuated in the new amalgamations

Gift to British Association

The Committee formed in Leicester in connexion with the meeting of the British Association there in 1933 had a surplus of £1,000 in hand after meeting all the local expenses of the meeting This sum has been handed over to the Association, to form the "Leicester and Leicestershire Fund, 1933" for the assistance of a student or students working for the advancement of science. The fund will be administered by the Council of the Association, and, when possible, assistance will be given preferably to a Leicester or Leicestershire student or worker. The Council, in accepting the gift, has expressed its appreciation of the action of the Committee "in thus confirming, in a manner without precedent in the history of the Association, their interest in the advancement of science".

Continuation of Empire Marketing Board Research Work

Mr. G. Gledhill, in the House of Commons on February 6, asked Mr. J. H. Thomas, Secretary of State for Dominion Affairs, if any arrangements have been made for carrying on the research work previously undertaken by the Empire Marketing Board. In a written answer, Mr. Thomas stated that such arrangements are being made. It is estimated that the cost of such research work in the financial year 1934–35 will reach £200,000, of which some £85,000 will be borne by other Governments of the Empire or by the institutions or industries concerned.

Announcements

Prof P M S. Blackett will give a course of three lectures on "Cosmic Radiation" at Birkbeck College, Bream's Buildings, E C 4, on Tuesdays at 6 p.m. commencing on February 20 Admission to the lectures will be free without ticket

The following appointments in the Colonial Agricultural Service have recently been made · C. A North-Coombes, to be agronomist, Department of Agriculture, Mauritius, C J. Lewin, chief agriculturist, to be director of agriculture, Northern Rhodesia, Capt J P. A Morris, deputy director of animal health, to be director of animal health, Northern Rhodesia

At the annual general meeting of the Royal Astronomical Society, held on February 9, the following officers were elected · *President*, Prof F J M. Stratton, *Vice-Presidents*, Sir Arthur S. Eddington, Mr John Evershed, Dr H. Spencer Jones and Dr. W J. S Lockyer; *Treasurer*, Mr. J. H. Reynolds; *Secretaries*, Mr W M. H. Greaves and Dr W. M. Smart, *Foreign Secretary*, Prof Alfred Fowler, *New Members of Council*, Prof. H. Dingle, Sir Frank W Dyson, Prof. H. F. Newall, Mr W H. Steavenson

In Nature of December 23, 1933, p. 963, under the title "Study of Canadian Coals", a note appeared referring to a report by R E Gilmore and R A Strong in the *Canadian Mining and Metallurgical Bulletin* (p 317, 1933), published by the Canadian Institute of Mining and Metallurgy. The journal was incorrectly quoted as the *Journal of Canadian Mining and Metallurgy*.

Applications are invited for the following appointments, on or before the dates mentioned:—A lecturer in mathematics at Darlington Training College—The Principal (Feb. 21) A museum assistant (male) at the Leicester Museum and Art Gallery —The Director (Feb 28). Staff tutors in psychology, political science, etc, at the University of London—The Joint Hon. Secretaries (Tutorial Classes), University of London, South Kensington, S.W.7 (March 1) A Wakefield lecturer in aeronautics at University College, Hull—The Registrar (March 7) A probationary assistant engineer in the Post Office Engineering Department—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1 (March 8) A Kennedy professor of engineering at University College, London—The Academic Registrar, University of London, S.W.7 (April 11).

Occurrence of Antirachitic Vitamin in Green Plants

As is well known, antirachitic substances arise through irradiation with ultra violet light It might be presumed, therefore that green plants, which are constantly exposed to the light of the sun would become rich sources of the antirachitic vitamin However, green plants or parts thereof, have hitherto been found to be poor in the above mentioned vitamin This may, perhaps, be ascribed to the fact that the plant material has been prepared in an unsuitable manner prior to examination It may also be however that the irradiation with sunlight has not been so intense as would have been supposed As the summer of 1933 in southern Norway was unusually rich in sunny days (sunny days recorded in Oslo May 25 June 28, July 30 and August 30) we considered it of interest to examine whether green plants this summer would show a larger vitamin D content than is usually the case

For this investigation was used meadow hay, consisting of Gramineæ and some clover, which was rapidly dried by a special quick-drying process (at 68 C for 2 hours—a process which it is now intended to use on a larger scale) The hay was afterwards pulverised The hay powder had a fresh, green colour, and yielded by extraction with ether in a Soxhlet apparatus 4 per cent of a deep green ointment like extract Daily doses of four milligrams of this extract brought about a satisfactory cure of rickets (method Poulsson and Løvenskiold[1]) The ether extract had, in other words, the same antirachitic effect as a high quality cod liver oil, containing about 250 Oslo units of vitamin D per gram This corresponds to 0 25 unit vitamin D per gram of hay powder

Some time ago, Kon and Booth[2] stated that vitamin D in butter showed a marked difference from the vitamin D found in cod liver oil and that obtained by ultra violet irradiation of ergosterol, whereas 80 per cent of the first was lost by the usual saponification, this is not the case with vitamin D from the other two sources We considered it of interest to examine whether this also applied to vitamin D in the above mentioned ether extract of green plants We brought about saponification by means of alcoholic potash lye 8 gm ether extract yielded 0 508 gm ether soluble unsaponifiable matter, that is 6 25 per cent This was diluted with inactive arachis oil until a quantity was obtained equal to that of the ether extract from which we started, namely, 8 gm Of the solution thus obtained, it was necessary to use 20 milligrams in order to obtain the same antirachitic effect as was found in the ether extract before saponification Vitamin D in green plants shows, accordingly, the same characteristics as Kon and Booth[2 3] have described for vitamin D in butter

We found it of interest, at the same time, to record the tintometric reading of the above mentioned solution of the unsaponifiable matter, in arachis oil This was found to be 10 blue units (which corresponds to a high quality cod liver oil) However, the tintometric reading, thus recorded, is probably not due to vitamin A, but to carotene, the precursor of vitamin A as the chlorophyll was removed by the saponification and the unsaponifiable matter showed a very pronounced yellow red colour 1,200 yellow and 20 red units were recorded as self colour on Lovibond's tintometer

Assay of Vitamin A

IN carrying out a series of assays by the curative method, of the vitamin A content of various samples of fish oils and dried milk it was found that in a large proportion of cases the weight curve did not give a reliable indication of the state of depletion of the vitamin A stores of the animal and that increase in weight after administration of a supplement could not always be ascribed to its vitamin A content

The experimental data obtained in these assays appeared to conflict with current ideas regarding the special influence of vitamin A on growth An investigation was therefore undertaken to ascertain (1) whether growth does in fact cease in vitamin A deficiency, and (2) the real significance of the loss in weight which is generally described as cessation of growth'

The evidence which has been obtained shows that when vitamin A is the only known factor absent from the diet, there is no cessation of growth, interpreting growth as increase in size This has been determined by measurements of length of the body in the live animal and by comparison of the lengths of the bones measured post mortem with Donaldson s values for the standard rat It would appear that vitamin A has no greater claim to be considered essential for growth *per se* than any other of the many factors which are responsible for increase in weight

The characteristic loss in weight which has been termed cessation of growth appears to be due entirely to pathological conditions arising from the vitamin A deficiency Even in animals killed at a stage when they are still increasing in weight, these conditions may be found on macroscopic examination

The diversity of the pathological symptoms which may arise during the preliminary depletion' period makes it impossible to secure uniformity in the experimental animals at the beginning of the test period This constitutes a source of error which makes the curative method of vitamin A assay of doubtful value It seems probable that the various discrepancies so frequently reported in such assays may find their explanation in the above observations

The results of this investigation, which were presented at a meeting of research workers at Aberdeen on December 18 last, will be published in detail at an early date

Designation of Heavy Hydrogen

THE frank acknowledgement of Prof Urey and his colleagues in NATURE of February 3 p 173 that the nomenclature of heavy hydrogen should not be decided by the wishes of the discoverers but by the convenience of physicists and chemists in general encourages me to say something in reply to their arguments

To physicists the most important point is perhaps the name to be given to the nucleus More than one physicist who was at Chicago last summer found it difficult to distinguish the spoken words neutron and deuton or deuteron The difficulty may be greater in England than in America all good Americans will realise that in England it always rains and everyone has a cold but in this country at least the danger of confusion seems to me to be serious and it is entirely avoided by using diplon

The names to be employed in chemistry will not be nearly so unpleasant as Prof Urey and his colleagues suggest They say that we should call $NH^1H^2_2$ di diplogen mono hydrogen nitride they would presumably say di deuterium mono protium nitride But the chemist would call it di diplo ammonia just as he calls $C_6H_4Cl_2$ dichlorobenzene and not di chlorine tetrahydrogen cyclohexacarbide Didiplo is no more cacophonous than di deuter didymium was accepted for many years as a satisfactory chemical name Moreover the compounds of H^2 will not always contain two atoms of it in the molecule

The objection that diplogen means making double is not really valid it means making diplon just as oxygen does not mean making sharp but making acids Diplon is the double thing just as proton is the first thing and is used in no other sense than as meaning the H^2 nucleus Deuterium or deutium means the second substance and deuteron or deuton the second particle and it may be argued that the second particle after the proton is the neutron whereas there is no doubt what particle is the double of the proton

The adoption of a new name to distinguish pure H^1 from the isotopic mixture does not seem likely to be widespread but if one is needed the obvious correlative to diplogen is haplogen as Prof Urey suggests and this seems to be a harmless word

Whatever decision may be reached on this question we can at least all agree to use the symbol D for H^2

N V SIDGWICK

Nuclear Spins and Magnetic Moments

A COMPARISON of the two lines of spectroscopic evidence bearing on the properties of the atomic nucleus raises some interesting questions and suggests new directions of research The magnetic moment of the nucleus can only be evaluated from hyperfine structure observations and then only in favourable circumstances The spin quantum number I can sometimes be obtained by both methods by the hyperfine structure method if the magnetic moment and its interaction with the optical electrons is sufficiently large and by the band spectrum method if the atom is one which forms an elementary diatomic molecule provided also that this gives rise to a band spectrum of which the rotation structure can be analysed Although each method is thus restricted in the scope of its application there are a number of cases in which both are applicable for example Li^7 F^{19} and Na^{23} for each of which the two values obtained for I are in agreement On the other hand, P^{31} Cl^{35} and K^{39} are amenable only to the band spectrum method the magnetic moment being presumably too small to give observable hyperfine structure whereas for many other nuclei (for example $Cu^{63, 65}$ $Cd^{111, 113}$ Cs^{133} $Hg^{199, 201}$ etc) the latter method only is applicable since no diatomic molecules giving rise to band spectra are known

The case of nuclei of even mass number is of particular interest No hyperfine structure has been detected for any of these although N^{14} shows some slight indications and such band spectrum observations as are available all give zero values for I with the exception of H^2 and N^{14} for which $I = 1$ (I is half integral or zero in every other known case) It would therefore be natural to assume as has generally been done that all nuclei of even mass number have $I = 0$ except H^2 N^{14} and possibly also Li^6 and B^{10} these four being the only nuclei of even mass number but odd atomic number

Such an assumption would however be quite unjustified on the basis of the present experimental evidence A zero value for I can only be established by band spectrum methods since the absence of hyperfine structure might alternatively be due to a small magnetic moment It is therefore unfortunate that the number of nuclei of even mass number for which diatomic band spectra are known is very small There are in fact only six four of which He^4 C^{12} O^{16} and S^{32} have mass numbers of the type $4n$ where n is integral and zero spins The other two H^2 and N^{14} have been referred to above They have I 1 but may very well be anomalous There are no others having mass numbers $4n + 2$ for which the band spectrum method is practicable at present The most promising appears to be Li^6 the difficulty here being the weakness of the Li^6_2 bands in comparison with those of Li^7_2 and Li^6Li^7 among which they lie The highest possible dispersion applied in a carefully selected region might offer some prospect of success

A survey of the remaining elements of this type shows that in every case one or more of the following obstacles bars further progress

(1) The isotope in question is too rare (for example O^{18})

(2) There are too many isotopes (for example $Te^{126, 130}$) giving rise to extreme complexity of band structure

(3) No suitable bands are known (for example Zn^{66} Se^{78})

(4) No bands at all are known (for example B^{10} Ne^{22} Ni^{58} Zr^{90} Ba^{138})

(1) and (2) would seem to be insuperable unless the technique of isotope separation can be greatly improved As to (3) and (4) the great variety of methods of excitation now available and the wide spectral range now open to photographic investigation give ground for hope that some of these band spectra may yet be discovered Whether or not an exhaustive search for them would be worth undertaking it is at least very desirable that spectroscopists working with such elements and their compounds should be on the look out for new band systems and should endeavour to ascertain the origin of any which may be found

W E CURTIS

X-ray Spectra of the *L*-series of Silicon and Silica

IN a preceding letter[1] we have shown that the *K* and the *L* spectra from aluminium in the metallic state are definitely different from those found with the non-conducting compound Al_2O_3. Analogous phenomena were found by Siegbahn and Karlsson also in the *K*-series of magnesium with the pure element and magnesium oxide (Mg O) (in publication elsewhere). The metals in these cases give broad bands with a sharp edge towards the shorter wave-lengths, which may be explained as transitions from the levels of the conduction electrons. The widths of the bands correspond fairly well with those calculated from the theory.

As it was of interest to see how the next element, silicon, which is a semi-conductor, behaves in this respect, we have taken spectrograms of the element and the oxide SiO_2. As is seen from Fig. 1, here also a broad band with a sharp limit towards the shorter wave-lengths is found for the element. In the band two maxima are visible, which are well pronounced and measurable in the photometric registrations. The wave-length of the edge is 125.5 ± 0.5 A., the maxima are at 134.3 ± 0.5 and 138.2 ± 0.5 A. The non-conducting compound SiO_2 gives a spectrogram of quite another character, with two strong lines at 130.7 A. and 139.5 A. (and a broader fainter line at 162 A.) as seen in the figure. This corresponds with the spectra of aluminium and the oxide Al_2O_3, where the oxide shows two well-marked maxima instead of the band at the pure metal.

Speed of 'Uniform Movement' of Flame in Mixtures of Carbon Monoxide and Oxygen

IN the year 1931[1] Prof. W. A. Bone and Mr. R. P. Fraser published figures for the speed of the 'uniform movement' of flame in moist (stated to be saturated at 12°–13°) mixtures of carbon monoxide and oxygen. Their values are represented by the crosses in the accompanying diagram (Fig. 1). In a paper published in 1932[2] we challenged both the absolute and the relative correctness of those values. Our results, for mixtures saturated at 13.1°, are indicated by circles in the diagram. Prof. Bone and Mr. J. Bell have repeated the experiments[3] and, whilst unable to confirm the earlier determinations, have obtained some (for mixtures saturated at 15°) that correspond with ours, within the limits of reasonable experimental error, as is shown by their curve reproduced in the diagram.

There remains, however, an outstanding difference. Prof. Bone and his colleagues consider that the maximum speed of 'uniform movement' of flame in moist mixtures of carbon monoxide and oxygen is obtained with a mixture of the composition $3CO + O_2$, whereas our results show that it is obtained with the mixture $2CO + O_2$. We do not offer any explanation for this difference, but suggest that a third party, sufficiently interested in the problem, should reinvestigate it.

Sheffield.

[1] *Proc. Roy. Soc.*, p. 542; 1931.
[2] *J. Chem. Soc.*, p. 1835; 1932.
[3] *Proc. Roy. Soc.*, 142A, 1; 1933.

SEEING that on p. 1836 of their paper (*loc. cit.*) Dr. Payman and Prof. Wheeler rightly stressed the fact that "with moist carbonic oxide the speed of flame varies considerably with the concentration of water vapour and is therefore subject to alteration from day to day if the temperature of saturation alters", it is curious to find them now citing an alleged 'correspondence' between some of two sets of flame speed measurements for moist $CO - O_2$ media saturated at 13.1° and 15.0° (water vapour = 11.3 and 12.75 mm.) respectively, as confirming the former. For when the difference between the two saturation temperatures is allowed for, the seeming 'correspondence' vanishes.

In repeating the earlier Bone and Fraser determinations—which, however, were for media containing 10.9 mm. only of water vapour—Mr. Bell and I discovered, what had not been recognised before, the importance not only of accurately controlling the hygroscopic condition of the moist $CO - O_2$ media, but also of ensuring a sufficiently large difference (at least 10°) between their saturation temperature and the temperature of the walls of the tube in which they are inflamed; and having taken special precautions to ensure this most necessary condition, we consider our results more reliable than any previous ones.

Seeing that they are largely influenced by environmental factors, the *absolute* values of such initial flame speeds in moist $CO - O_2$ media are of no fundamental import, the real question being where, under given conditions, the maximum speed-point lies on the speed-composition curve. In view of the considerable CO_2-dissociation in CO-oxygen flames, the maximum speed is to be expected with an excess of carbonic oxide. Anyone studying our recent results will (I think) agree with our conclusion that, *provided all due precautions are taken to ensure accuracy in the measurements*, "with moist media, saturated at 15° [it] is attained at the $3CO + O_2$ composition".

Chladni Plates at High Frequencies

IN order to make a high-frequency oscillator for brass plates, I wound a suitable inductance around a nickel rod twelve inches long and one eighth of an inch in diameter. The inductance was excited at 15,000 vibrations per second from an audio vacuum tube circuit connected through a power amplifier. The nickel rod was in a vertical position and the square Chladni plates were balanced upon it. The figures shown in the photographic reproductions (Fig. 1) were formed in this way.

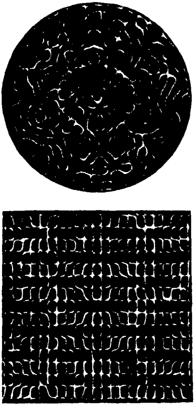

FIG. 1.

When a circular plate was balanced on the rod, only circular nodal lines were formed. I therefore clamped the circular plate at the centre and pressed the oscillating nickel rod against the under side of the plate near the edge.

Calculation shows that the plates oscillate at a submultiple of the oscillation in the rod. They cannot take up such a high vibration as 15,000 per second.

Influence of Light on Paramagnetic Susceptibility

SELWOOD[1] has recently published the result of his investigation on the influence of the absorption of light on the paramagnetic susceptibility of certain solutions, in which he fails to confirm our observation of the increase of susceptibility under such conditions. He finds, in agreement with Gorter's observation, that there is a gradual diminution of susceptibility of the solution which can be attributed to a rise of its temperature, due to absorption of light. The method used by him is that due to Decker, in which a test piece of glass of nearly the same susceptibility as the paramagnetic solution is suspended from a torsion head between the pole pieces of an electromagnet. The sensitiveness of his apparatus is claimed to be 0.005 per cent.

It appears to us that besides the sensitiveness of the apparatus used in measuring the change in susceptibility, there is another factor involved, namely, the magnitude of the change ΔK produced by absorption of light. If n_2 is the number of ions per c.c. in the excited state and p_1 and p_2 are the magnetic moments of the ion in the ground and excited states respectively, then

$$\Delta K = \frac{2p_1}{3kT} n_2 (p_2 - p_1),$$

and n_2 will be proportional to the amount of light energy absorbed. In the modified U-tube method used by us in our recent experiments, an account of which has been sent to the *Philosophical Magazine* for publication, we used a solution of $CrCl_3$ containing 0.078 gm. of Cr^{+++} per c.c. with $K = 13.42 \times 10^{-6}$, the horizontal portion of the U-tube is a capillary tube of bore 1.8 mm., which was filled partly with the solution, and the meniscus placed between the poles of an electromagnet of field strength of about 40,000 gauss, and the light from a mercury arc was focused on it. About 81 per cent of the light was absorbed in the solution and the change of susceptibility produced was equivalent to an increase of volume susceptibility of air due to an increase in pressure corresponding to a 2.4 cm. column of water, that is, $\Delta K = 7 \times 10^{-11}$ c.g.s. units. The rise of temperature of the solution was about 0.001° C. per sec.

From our experience, it appears that in Selwood's experiment the amount of light energy absorbed by the solution at the boundary of the test piece, where the magnitude of the change ΔK alone is of importance, was too feeble to produce any measurable deflection with apparatus of the sensitiveness of that used. In the course of our investigation, we have employed a similar type of apparatus to that described by Selwood, but we enclosed the paramagnetic solution in the glass test piece and the outer solution was of colourless $CeCl_3$; with this arrangement we obtained negative results.

Selwood's remark about the difficulty of explaining the increase of susceptibility observed in didymium nitrate as due to a temporary breakdown of *l*-coupling is justified We ought to have mentioned specially that our theory applies only to ions of the iron group

The writing of this letter was delayed due to the absence of one of us in Europe

Modulation of Very Short Radio Waves by Means of Ionised Gas

ION densities of the order of 10^{11} ions/cm ^{3}, such as occur in gases in glow discharges under the usual conditions, are of the correct magnitude to affect very considerably the index of refraction and absorption of these media for ultra-short radio waves It has been found that the intensity of a beam of radiation of wave length 9 5 cm can be easily modulated by causing it to traverse such an ionised gas in which the ion density is caused to vary

A glow discharge tube of dimensions equal to several wave lengths was used to provide the ionised medium It was connected to a direct current supply in series with an audio frequency voltage The D C supply was used to maintain the discharge at the required level and the audio frequency to provide the variations of ion density for modulation purposes This tube was placed in the radio beam between the transmitter and receiver while music or speech modulation were impressed on it The fidelity of the sound thus received was, as closely as could be noted by the ear, a good replica of the output of the audio amplifier which was impressed on the ionic modulator

Modulation was obtained also by causing the beam to be reflected from an approximately flat surface built up of glow discharge tubes in the form of concentric rings However, the degree of modulation was not as great in this case as when the beam was made to traverse the ionised medium It appears that the modulation is due principally to absorption, although reflection, scattering and refraction also play a part

This method of modulation yields more pure amplitude modulation than does direct modulation of the oscillator, since the frequencies of ultra-short wave generators, such as Barkhausen-Kurz tubes and magnetrons, are quite susceptible to variations in the applied voltages

The oscillator used in this work consisted of a small split anode magnetron, the split anode being 4 mm in diameter and 7 mm in length. The receiver was a crystal detector coupled to an audio amplifier Parabolic reflectors were used with both transmitter and receiver.

Further details will be given in other publications

Radiation and Ionisation produced by High Energy Electrons

ON the basis of Dirac's theory, Heitler and Sauter[1] have calculated the probability that high energy electrons in their passage through matter emit a quantum of energy comparable to their own These results, as they recognise, are in contradiction to the measurements of Anderson[2] and Blackett and Occhialini[3] on the energy losses of high energy particles The rate of ionisation of a gas by an electron as calculated from Dirac's theory agrees closely, however, with the experimental results

These results indicate either that Dirac's equation cannot be applied to high energy particles or that the structure of the nucleus, finite size and finite potential within its boundary, plays a rôle The rate of ionisation is independent of the potential within the nucleus, whereas the probability of radiation for high energy electrons is decreased in the ratio of the value of the potential within the nucleus to the energy of the electron expressed in equivalent units The finite size plays no part until the energy is such that the waves scattered from the different parts of the nucleus can interfere With this correction to the nuclear model, Dirac's theory gives results which are in harmony with the experimental evidence, and thus seems to be applicable to processes which occur outside the limited region of the nucleus These calculations, which were made by the Born method of successive approximations, were carried to a first order

This decrease in the rate of radiation by high energy electrons, compared to that calculated on the assumption of a Coulomb field for the nucleus, is accompanied by a corresponding decrease in the rate of production of pairs, electron and positron

The Term 'Mesolithic'

FOR many years it was the custom to regard the line of separation of the Palæolithic and Neolithic periods as roughly corresponding to the geological division between the Pleistocene and Holocene , and even Mr Peake's excellent historical summary (NATURE, Jan 20, p 104) does not make it clear why this position was ever abandoned It is unsatisfactory, and a source of confusion, that the term 'Neolithic' should be used in a broad sense by one generation, and in a very narrow one by the next—that in one case it covers several thousand years in many different lands, while in the other it varies enormously in length in different countries, and in England (where the term originated) it is whittled down to a few decades, with some risk of complete disappearance.

Of course, no one questions that the cultures of Tardenois, Maglemose, etc , are very distinct from that of the 'Age of Polished Stone' , but that could easily have been overcome by a division into Early and Late Neolithic, or, for those who are not happy without new names, into 'Mesolithic' and 'Metalithic' periods. We could then have gone on applying 'Neolithic' in a comprehensive sense to submerged forests, the lower strata of Tilbury and other docks, the Blashenwell tufa of Dorset, and other cases in which no precise dating is at present possible.

Is it altogether too late to return to this convenient arrangement? Such a conservative course may not commend itself to those professional archæologists to whom even such a sesquipedalian invention as 'Epipalæolithic' has no terrors; but it would be a comfort to the general reader, and to those who, like myself, occasionally wander over the border between geology and archæology.

HENRY BURY.

The Gate House,
Bournemouth West.

I AM grateful to my friend Mr. Harold Peake for dealing with this question of the term 'Mesolithic' so fully. Unfortunately, I am unable to doubt that this term has now received wide acceptance among archæologists. But this cannot alter the fact that from the point of view of a correct nomenclature it must be wrong to designate as 'mesolithic' specimens which are agreed on all sides to be referable to the latter part of the Stone Age It is as if I were to be asked to acquiesce in calling 'mid-Victorian', circumstances, or objects, relating to the end of that epoch I cannot believe that it is beyond the wit of archæologists to find some term, descriptive of the period and artefacts in question, which will not violate common-sense. Mr. Peake will perhaps allow me to express doubts as to whether I am the only archæologist who objects to the term 'mesolithic' But, even if his dire prophecy is true, I am cheerfully prepared to remain in a minority of one in this matter

Inheritance of Egg-Colour in the 'Parasitic' Cuckoos

PROF PUNNETT[1] has suggested that Prof Wynne-Edwards' ingenious hypothesis[2] for explaining how the *gentes* of 'parasitic' cuckoos may be kept distinct despite their promiscuous or polyandrous mating habits could be replaced by the assumption that it is the Y-chromosome of the mother which carries the factor assumed to determine the *gens* to which the offspring belong It is not clear that such an alternative theory has any advantages over the original one (though it might have, were the degree of mimicry invariable). It seems slightly less plausible genetically owing to the paucity of known Y-chromosome genes, and has the distinct disadvantage that it involves the offspring all belonging to the same *gens* as the mother, the "mechanism . . provided for stabilising the population by damping the fluctuations caused by the host species" which is inherent in Prof Wynne-Edwards' theory is therefore lacking.

Both Prof Wynne-Edwards and Prof Punnett assume that the different *gens* factors postulated comprise a single series of multiple allelomorphs. The latter stresses this as an essential corollary, and considers as an objection to the hypothesis the fact that in the domestic hen egg-colour is determined by several independent autosomal genes But the assumption of several pairs of sex-linked factors would explain the observations even better than a single multiple series, since it would account for the imperfection of mimicry found in areas where one species of cuckoo 'parasitises' several hosts Further, Prof. Wynne-Edwards mentioned the probability that autosomal modifiers also exist Prof. Punnett has cited one of many cases in which genes presumed to be phylogenetically homologous are situated on different chromosomes in different species. The assumption of a limited number of sex-linked pairs of genes rather than a single series would therefore seem to remove the only genetical objection raised by Prof Punnett.

Possible Chemical Nature of Tobacco Mosaic Virus

DR J CALDWELL[1] has criticised some of our statements on the possible chemical nature of the virus of tobacco mosaic. We must point out that the essential precipitant used in the Vinson and Petrie method is not basic lead acetate but neutral lead acetate We are also quite aware of the fact that the addition of two volumes of acetone to one of aqueous $M/1$ KH_2PO_4 solution produces a heavy precipitate of white rhombic crystals, but as Vinson and Petrie and ourselves were concerned with an $M/15$ solution of this salt, Caldwell's criticism is irrelevant. If acetone (two volumes) be added to an aqueous $M/15$ solution of KH_2PO_4 or to an eleuate prepared from healthy sap, only a faint white opalescence makes its appearance and a slight precipitate settles after many hours

It is mentioned in our communication that the crystalline fraction of the acetone precipitate is mainly composed of phosphate, but we still maintain that, although infective, it contains no nitrogen. The statement that the *N. glutinosa* method is a quantitative one for determination of virus is misleading, as at best the method can only give a very rough approximation of the relative concentration of the virus in samples of high dilution.

A Tame Platypus

WITH reference to the platypus mentioned in NATURE of September 16, 1933, p 446, Mr. R Eadie, who has attended to the animal, informs me that it is still alive and has been, at the date of writing, in captivity for 282 days.

The references to diet require modification The daily ration is at present 10 ounces of worms, 50 small tadpoles, wood grubs two or three times a week, and 2 eggs—usually duck eggs—every night. The eggs are prepared in the form of a batter and then steamed. When cold the mass is stirred with a fork until it consists of pieces the size of a large pea. Mr. Eadie estimates the quantity of food consumed at fourteen ounces daily. The weight of the platypus at the time of writing is three and a quarter pounds.

Research Items

Mental Tests of the African. The difficulties and special methods requisite in the study of the African by the employment of intelligence tests are discussed by Dr. R. A. C. Oliver, Carnegie fellow for educational research in Kenya, in *Africa*, vol. 7, pt 1 Dr. Oliver has been engaged in the study of general intelligence, and in a lesser degree of musical talent, in Kenya natives. His general tests were devised to measure the intelligence of natives who had received some schooling, and were non-verbal tests, the problems being presented in pictures and other symbols. The kind of test to be used varies with the feature of African mentality in which we are interested; but we ought to know more about the African's abilities in specific activities and their special strength or weaknesses The type of test will also depend on education and the language situation. Two lessons are suggested by experience first, that it is highly desirable to precede the test with a demonstration and practice; and secondly, that the time allowed should be unlimited or ample An application of a general intelligence test to 124 pupils of a secondary school for European boys and 93 pupils of a secondary school for African boys in Kenya produced two main facts The average mark of the African was 85 per cent of the average mark of the European, secondly, 14 per cent of the Africans gained a mark as high or higher than the average European mark. This leads to a conjecture that, comparing the variability with that of Europeans, a small percentage of Africans might be capable of a university education; a larger percentage might complete the secondary school course; a still larger percentage might undertake a few years in the secondary school and the mass of the African people might take a full primary school course

European Bitterling spawning in American Mussels. The bitterling (*Rhodeus amarus*), a European minnow, was introduced into Sawmill River, New York, in or before 1925, and after surviving for a few years disappeared. The suggestion was made that lack of suitable mussels, within which the eggs might be deposited, determined the disappearance of the bitterling. C. M. Breder, however, has made special observations of bitterlings and American mussels, kept together in an aquarium (*Copeia*, 1933, p. 147). Although actual oviposition was not observed, the courtship behaviour of the fishes agreed with the descriptions in European aquarium journals, and when one of the mussels was opened four days later, seven bitterling embryos were found in the gill folds, embedded as described for European mussels. The first opened mussels belonged to the species *Unio complantus*, but two specimens of another species, *Anodonta cataracta*, contained three and ten embryos respectively. Since in Europe *Rhodeus* is known regularly to use both *Unio pictorum* and *Anodonta cygnea*, it would seem that a considerable variety of mussels is available for the peculiar reproductive habits of the bitterling, and that other causes than the unsuitability of the mussels must be sought to account for the disappearance of the specimens set free in an American stream.

Fossil Insects from the British Rhaetic and Lias. The Trustees of the British Museum issued during 1933 the third of their series of publications on fossil insects The present work is in the form of a small handbook entitled "The Panorpoid Complex in the British Rhaetic and Lias" by Dr. R J Tillyard. The material upon which it is based consists of nearly one hundred specimens, contained in the British Museum, with a further eleven specimens in the Museum of Practical Geology. It includes examples belonging to the orders Neuroptera, Mecoptera, Paratrichoptera, Trichoptera and Diptera These groups, along with the Lepidoptera (not represented among the material) form a related assemblage of orders which constitute what Dr. Tillyard has termed the Panorpoid Complex. They centre around the primitive order Mecoptera, and it is to this group that most of the specimens dealt with in this memoir belong The Mecoptera in the collection include nine species, embracing four genera, of which three of the latter were previously undescribed The Neuroptera comprise two new species, each representing an already known genus, while the only Paratrichopteron forms the type of a new family—the Liassophilidæ The Trichoptera are represented by fourteen specimens, all pertaining to species (mostly new) of the genus *Necrotaulius*. Of the Diptera there are only three examples: these are Tipaloid forms which are referred to the new genus *Liassotipula* and the new species *anglicana* As is usual among British Museum publications, this work is well printed and admirably illustrated It is obtainable through booksellers or from the Museum, price *5s*.

Studies on Cuticle. V B. Wigglesworth has recently recorded observations on the cuticle of the blood-sucking bug, *Rhodnius* (*Quart J. Micr Sci.*, 76, Part II, 1933) The cuticle consists of two primary layers—a very thin epicuticle and a relatively thick endocuticle traversed by fine pore-canals The epicuticle is composed of material (cuticulin) the chemical properties of which are like those of the cutin or suberin of plants The endocuticle is composed of protein and chitin, and is made up of two layers. The nymphal stages of *Rhodnius* ingest from six to twelve times their weight of blood at a single meal and the adults may take three times their own weight. The abdomen is therefore capable of great distension, which is accomplished in the nymph and the adult in a different way. In the former the endocuticle is flexible and free from cuticulin, and in the fasting nymph the overlying epicuticle is thrown into deep folds When the abdomen is distended with blood the endocuticle is stretched and attenuated and the folds of the epicuticle are smoothed out. In the adult the outer part of the endocuticle is permeated with cuticulin, is rigid and can not be stretched. A deep longitudinal fold or pleat in the lateral wall of the abdomen permits distension of this region. The dermal glands and their ducts, the structure of the epidermis, including the cells crowded with spheres of uric acid, the process of moulting and the formation of new cuticle are described. It is suggested that the œnocytes, a new generation of which arises at each moult (except the last) from embryonic cells in the epidermis, synthesise some of the nonchitinous constituents of the cuticle during moulting and of the egg-shells during maturation of the ova.

Research on Lichens A paper by Miss A Lorrain Smith in vol. 18, pt 2, of the *Transactions of the British Mycological Society* reviews recent lichen literature (pp 93–126) The author describes several works on lichens which have appeared during the last two years Perhaps the most monumental of them is Zahlbruchner's "Catalogus Lichenum". Contributions to our knowledge of gonidia, parasymbiosis, lichen structure, soralia, isidia, cephalodia, and apothecial reproduction are reviewed critically. The section on physiology collects some very useful knowledge about lichen acids, and paragraphs on the rate of growth, lichens as pests and gall formations are very interesting Systematy and ecology are treated at considerable length, and a bibliography of nearly three hundred references is of great benefit to all students of lichens

Entomogenous Fungi of Egypt. A short bulletin (No 120) of the Technical and Scientific Service of the Ministry of Agriculture for Egypt deals with some entomogenous fungi in Egypt (by Dr R M Nattrass, pp 1–9, Cairo, 1932) The paper describes various fungi which attack Egyptian insects. Species of the genera *Empusa*, *Aspergillus*, *Beauveria*, *Metarrhizum* and *Mucor* are involved, and some of their cultural characters are given. Inoculation experiments are described, but there seems little likelihood that fungi may be used as a method of control for insect pests. The work is admittedly of a preliminary nature, but warrants extensive investigation for the sake of the mycological problems involved

West Highland Tectonics. At the meeting of the Geological Society on January 10, Prof E. B Bailey presented a valuable paper on the structure of the Loch Leven to Glen Roy district Study of the current-bedded quartzites of Loch Leven has confirmed various deductions previously recorded and has led to certain new conclusions T Vogt, S Buckstaff and O N. Rove are found to be correct in claiming the Eilde Flags as the oldest member of the Eilde Flag–Cuil Bay succession. R. G Carruthers is correct in placing three quartzites and three mica-schists between the Eilde Flags and the Ballachulish limestone The gigantic recumbent folds of the district tend to retain their inverted limbs intact and to lose their normal limbs by drag The Am Bodach quartzite is found to belong to the Eilde, and not to the Glen Coe, quartzite, it occurs in a recumbent fold that has its roots four miles farther east The quartzite of the eastern Stob Coire Easain, above Loch Treig, is also Eilde quartzite and marks another large-scale inversion The strong folding of the Fort William slide in Glen Roy, first recognised during a preliminary traverse by R. G Carruthers, has now been established in detail

The Quinhydrone Electrode. The increasing use of the quinhydrone electrode makes a study of its normal potential of importance, and in this connexion some experiments by Harned and Wright (*J. Amer. Chem. Soc*, December 1933) are of interest. The cell: Pt / Quinhydrone, HCl(0 01*M*) / AgCl / Ag, without liquid junction was used, and details as to the preparation of the materials and the technique, the cell being operated in vacuum (a necessity for the silver electrode), are given. By combining the results with those for the cell H_2(1 atm.)/HCl(*m*)/AgCl/Ag, previously investigated, the electromotive forces of the important cell Pt/Quinhydrone, HCl(*m*)/H_2(1 atm) are calculated, and thence the normal potential of the quinhydrone electrode. Values were found at temperatures from 0° to 40°, although side reactions quickly destroy the equilibrium at temperatures above 30° The values for the normal potential of the quinhydrone electrode are expressed in a quadratic equation as regards dependence on temperature, and it is shown that they agree to 0 2 millivolt with those interpolated from the earlier measurements of Biilmann and his collaborators, who measured the potentials directly against the hydrogen electrode The new results are considered the best available at the present time Some peculiarities in the behaviour of the cells are of interest

Vitamins from Egg Yolk and Fish Oil. Dr. N K Basu, working in Calcutta, reports in communications to the Editor that he has obtained vitamin A by irradiation of a sterol isolated from egg yolk, and also that he has succeeded in isolating crystals of vitamin D from a fish oil The egg-yolk sterol has a melting point of 62°–67° C., on irradiation with ultra-violet light of wave-length 2750-3000 A, a substance reacting strongly with antimony trichloride was obtained Spectroscopic examination of the product showed the maximum absorption to be in the ultra-violet at 3280 A, and the blue colour developed with antimony trichloride showed absorption bands at 5720 A. and 6200 A. Crystalline vitamin D was isolated from the oil of *Notopterus chital*, a fish common in Bengal A concentrate obtained from the oil was distilled at a temperature of 120°–140° C and at a pressure of 1 mm On cooling, this crystallised in the form of needles having a melting point of 117°-120° C and showing maximum absorption at 2650 A the crystals gave no precipitate with digitonin The final confirmation of the identity of these two products with vitamins A and D respectively will, of course, depend on the results of the biological tests, which are not reported. The properties of the crystals obtained from the fish oil agree fairly well with those of calciferol It is more difficult to correlate the production of vitamin A from a sterol with the fact of its formation from carotene in the body.

Radiation from Variable Stars The very delicate operation of measuring the radiation from stars with the aid of specially constructed thermocouples attached to the 100-in. telescope at Mount Wilson has previously been mentioned in NATURE (123, 425). The results of observations by E. Pettit and S. B. Nicholson on variable stars during the period 1921–27 have now been published in the *Astrophysical Journal* (78, 320). Observations were made on twenty-one long-period variables, nine irregular variables, two Cepheids, and on Algol. In the case of the long-period variables, it was found that on the average the real energy maximum occurs about 50 days later than the visual light maximum, though the variations of temperature are approximately in phase with the light curves. The average temperature range is from 1800° K. to 2350° K., and the coolest star observed (χ Cygni) varies from 1630° K. to 2260° K. In the case of the two Cepheid variables η Aquilae and δ Cephei, as well as in Algol, the changes in radiometric magnitudes are in phase with their light curves This result is to be expected, since the maximum of energy for stars of this class is in the visual region of the spectrum.

A Velocity-Modulation Television System

MANY of the investigators who are seeking at the present time to develop a practical system of television make use of the cathode ray oscillograph tube in one form or another, since the electron beam in such a tube provides an easily controlled means of scanning the picture to be transmitted. At the receiving end, the cathode ray tube is employed to build-up the received picture by varying the intensity of the beam in accordance with the light and dark portions of the picture. The ordinary type of cathode ray tube, however, gives only a small range of intensity control without the accompaniment of loss of focus of the spot on the fluorescent screen, and special electrode systems have to be arranged to obtain good intensity modulation in this manner. As an alternative to this method, the intensity of the cathode ray beam may be kept constant but its tranverse velocity may be varied as it moves over the picture, the beam being speeded up over the dark portions of the picture and slowed down over the light portions. The corresponding motion of the cathode ray beam at the receiving end thus gives varying illumination according to the speed of travel of the spot on the fluorescent screen, and with the aid of the phenomenon of persistence of vision, a true impression of the shades and contrasts in the picture received is obtained.

The conception of this velocity modulation principle, or variable-speed cathode ray television, dates back to 1911, when it was described in a British patent by B. Rosing. Since that date the principle appears to have fallen into oblivion until it was revived in Germany by R. Thun in 1929. The first practical realisation of the method was achieved by M. von Ardenne in 1931 and reference was made to this work in NATURE of October 7 last (p. 573).

During the development of cathode ray oscillograph tubes for general scientific and technical purposes, the staff of Messrs. A. C. Cossor Ltd. realised the possibilities of the above system of television, and an account of the development work carried out during the past eighteen months was presented in a paper entitled "A Velocity-Modulation Television System", read before the Wireless Section of the Institution of Electrical Engineers by Messrs. L. H. Bedford and O. S. Puckle on February 7.

Consideration of the basic principles outlined above shows that it is impossible to realise a velocity-modulated picture from a uniformly scanned object; the scanning at the transmitter must also be of the variable-speed or velocity-modulated type, and must therefore be carried out by a cathode ray. It follows that a cathode ray oscillograph must serve as the source of light at the transmitting end, and, with oscillographs of the ordinary low-voltage type, the conditions of scanning-light economy will restrict the picture subject matter to cinematograph film material. This, however, is not considered to be a disadvantage of the method; many of the television systems being developed at the present time make use of a film as an intermediary, and processes are being devised in which the interval between the photography of the subject and the projection of the picture through the transmitter is reduced to the bare minimum.

The transmitting arrangements described by Messrs. Bedford and Puckle comprise the projection of light from the fluorescent screen of the oscillograph through the film picture on to a photoelectric cell. The output of the photo-cell amplifier operates, through a screen grid valve and a thyratron, an electrical time base circuit which supplies the potential difference to one pair of the deflecting plates of the oscillograph. The light from the cathode ray tube is thus swept in a straight line across the picture with a velocity which varies according to its transparency at different points. At the end of each scanning line, the discharge of the thyratron provides a 'fly-back' action to the spot sufficiently rapid to be invisible. Simultaneously with this operation, a second valve and thyratron circuit provides a traversing time-base potential difference to the second pair of deflecting plates of the oscillograph tube. By this means the scanning line is traversed across the picture in successive steps.

From this description it will be realised that an image of the picture being transmitted is built up on the fluorescent screen of the cathode ray oscillograph, and this is found to be a useful feature of the system for monitoring purposes. Furthermore, for the reproduction of the image on the screen of another oscillograph tube at a distant receiving station, it is merely necessary to transmit to the second tube the voltages being applied to the two pairs of deflecting plates of the first tube. If these voltages are sent through two separate channels, the received picture is automatically synchronised with that at the transmitting end.

The authors of the paper referred to above have modified this arrangement to some extent, however, to enable all the intelligence to be sent along a single channel. Using a picture frequency of 25 per second with a detail corresponding to 120 or 160 scanning lines, the transmitted signals require a frequency band of the order of 240 kilocycles per second; and special amplifiers have been developed to give uniform amplification over this range. The size of the picture received depends upon the deflector voltages which may be applied to the oscillograph electrodes, and it is anticipated that future design and manufacture will enable a suitable receiver tube with a 9-inch screen to be produced. Among the advantages of the method described above over that employing intensity-modulation are the increased picture brightness for a given receiving oscillograph and the concentration of detail in the light portions of the picture.

Although Messrs. Bedford and Puckle's experiments have so far been limited to transmission over wire lines, no particular difficulty is anticipated in applying the necessary signals to radio transmission, at least on the ultra-short wave-length of a few metres where such a large frequency band as 240 kc./sec. may be permitted. At the reading of the paper, a cinematograph film was shown illustrating typical pictures received in a laboratory test of the whole system. Among the features brought out in this demonstration was the fact that, when required to obtain a better contrast ratio in the received picture, intensity modulation may be superimposed with advantage upon the velocity-modulation signals, and means of achieving this very satisfactory combination are being investigated.

Astronomy and International Co-operation

IN his presidential address to the Royal Astronomical Society at its annual meeting on February 9, Prof. F. J. M. Stratton sketched the development of schemes of international co-operation in astronomy during the last hundred years. The first such scheme was that of the Berlin Academy for a chart and catalogue of stars down to the 10th magnitude, to be completed by a number of continental astronomers by 1828; it was actually not completed until 1858. Along the same lines were the plan of the *A.G.* zone catalogues drawn up in 1869, and later still the more ambitious photographic "Carte du Ciel" set on foot in Paris in 1887 and not yet completed. The founding of the "Centralstelle" for astronomical telegrams and the various activities of the Astronomische Gesellschaft kept the Germans for many years the chief organisers of joint astronomical schemes, but after the Permanent Commission of the Carte du Ciel had been established with its occasional gatherings of astronomers at Paris, the headquarters for international astronomy of position shifted to France.

In Paris were held conferences on fundamental stars and on co-operation in the work of preparing national ephemerides; there too were established the Bureau de l'Heure and the Bureau des Poids et Mesures. The United States became active in this sphere at the Washington Conference of October 1884, when the meridian passing through the centre of the transit instrument at the Observatory of Greenwich was adopted as a single prime meridian for all nations. From the United States, too, came the impetus which founded the International Solar Union; this body performed for solar and stellar physics the same function as that of the Permanent Commission of the Carte du Ciel for the older astronomy.

The War cut right across the older organisations, and in 1919 the International Astronomical Union was founded in an attempt to start once again the sadly crippled forces of co-operation. The new body set up more than thirty committees to deal not only with the work inherited from the earlier organisations but also with many branches of astronomy, such as double stars, which had remained unprovided for owing to the casual way in which the earlier schemes had come into being. Over the whole field of astronomical research the Union, without in any way interfering with individual liberty, has endeavoured to provide a common meeting ground for the discussion of problems and the preparation of schemes of mutual co-operation. Valuable reports from the various committees have been published, notably on standard wave-lengths, stellar photometry and stellar classification; these have been published in the volumes of transactions freely distributed to observatory libraries.

Grants in aid have been made by the Union for the publication of tables and observations, for printing volumes of the "Carte du Ciel", for the Bureau de l'Heure at Paris and the Bureau of the Variation of Latitude at Mizusawa, for computations in connexion with the recent opposition of Eros. (The Astronomer Royal gave an account of the progress of this work at the same meeting of the Royal Astronomical Society—a valuable illustration of the work of the Union.) In all, grants of more than £14,000 have been made by the Union to its committees. The present financial world crisis has not left the Union unscathed, but it is continuing "alive and responsive to new needs and changing conditions, a powerful support of astronomy in all its branches and a centre of co-operative good will among the astronomers of the whole world".

History and Management of the Hope Farm, Jamaica

TO the British Empire, the problem of milk production in the tropics is of paramount importance. It is a problem which at the present moment faces both the administrators and their agricultural advisors in each one of the British tropical dependencies and in India. The "History of the Hope Farm and Part 1 of the Jamaica Herd Book of Pure Bred Cattle" by H. H. Cousins, is an outstanding contribution to this subject (Pp. vi+308+59+54 plates. Kingston, Jamaica: Government Printing Office, 1933). This Jamaican estate, becoming derelict, passed in 1909 into the hands of the Government and represents a somewhat unusual incident in Government operations by which an officer was called upon to justify, as a commercial concern, the acquisition of land as public property, practically without capital and dependent upon the earnings of the enterprise for its development. The assets of the Farm now show a gain of nearly £16,000, or an annual increase averaging £751 from 1910 until 1931.

What will mostly appeal to livestock men in the tropics is the detail which has been put forward concerning the productivity of cows of many pure breeds and of their crosses. Many of the imported cows were of British breeds and came from Great Britain or North America. From India came the Nellore, Sahiwal and other Zebu cattle. The lifetime history of each cow is clearly set out. Several experiments in inbreeding were attempted, but the only one which appears to have had any measure of success involves the mixture of the Zebu with the Jersey. The excellent photographs, studied in conjunction with the records of the animals concerned, provide useful information.

An interesting point in the organisation of this farm, and one which may be commended to the attention of Colonial administrators, relates to its finances. It was recognised from the start that this enterprise should be operated on a separate account at the Treasury. The approval of the Secretary of State was obtained for this departure from the usual system of departmental finances, whereby expenditure was 'debited' and the revenue 'credited' to the general account without any direct connexion between the two. The method adopted for Hope Farm allows that freedom of decision which is essential for the proper conduct of a farm.

More important still is that where genetic experiments with cattle are concerned, the financial establishment of a farm should be along these lines, in order that there may be continuity in method over that period of years which is demanded by the nature of the investigation. Too often has a change in the policy of the Government resulted in the 'axing' of an inquiry of this nature. Twenty-five years is not too long for such an experiment, upon which it may be a waste of time and money to embark unless there is some guarantee that the work will be carried forward. Mr. Cousins has achieved this and it is greatly to his credit and to his foresight at the time the Farm was established. After serving the Colony for a quarter of a century, he is now retiring from the post of Director of Agriculture. This report represents an important section of his work and he must indeed be a proud man who can leave such a memorial of service behind him.

University and Educational Intelligence

CAMBRIDGE.—Dr. P. E. Vernon, of St. John's College, has been appointed to the Pinsent-Darwin studentship for three years.

J. A. Steers, of St. Catharine's College, has been appointed to represent the University at the International Congress of Geography to be held in Warsaw in August–September of the present year.

At Pembroke College, J. W. F. Rowe, University lecturer in economics, has been elected to a fellowship.

SHEFFIELD.—Mr. Arthur Pool has been appointed lecturer in mental diseases.

The Council has received a gift from Dr. Foggo of old medical books, anatomical plates, surgical instruments, etc., belonging to the late Dr. Rooth, of Dronfield.

DR. H. E. C. WILSON, lecturer in physiology in the University of Glasgow, has, with the approval of the Government of India, been appointed professor of biochemistry and nutrition at the All India Institute of Hygiene and Public Health, Calcutta.

APPRAISEMENT of fitness for admission to secondary schools is a task which each year taxes the ingenuity of local education authorities. The technique evolved in grappling with its difficulties in the West Riding of Yorkshire is set forth in some detail in a report by the Education Officer, on the examination for county minor scholarships of some fourteen thousand children of ages 10–12 years, of whom about one seventh were successful. To the written examination in English and arithmetic there was added this year a group intelligence test taken by all candidates in place of an oral test. This was favourably reported on by Prof. G. H. Thomson and was found helpful in dealing with 'border line' cases. The chief examiner's report includes a careful estimate of the evidence afforded by the answer papers in arithmetic of divergence in mental capacity between boys and girls and an expression of a fear "that too often the girls' natural clinging to painstaking methods is reinforced by their training, instead of being to some extent supplanted by the development of that initiative so necessary—even for women—in every walk of life". The report on the examination in English quotes a number of surprising and psychologically interesting 'howlers'. The following essay on "The Importance of Little Things" affords (with many others) evidence, the examiner believes, of ill-assimilated health talks: "An atom is a small animal. It has no legs or arms but has a mouth and means of indigestion. Without these we cannot live: scientists have proved it".

Science News a Century Ago

Baldwin's Locomotive *E. L. Miller*

On February 18, 1834, Matthias W. Baldwin, the founder of the Baldwin Locomotive Works, Philadelphia, completed his second locomotive, the *E. L. Miller*. His first locomotive, *Old Ironsides*, completed in November 1832 for the Philadelphia, Germantown, and Norristown Railroad, was a four-wheeled engine modelled on the plan of Stephenson's engines. The *E. L. Miller*, built for the Charleston and Hamburg Railroad Co., however, was a six-wheeled engine with two driving wheels 4½ ft. in diameter and four smaller wheels attached to a swivelling or 'bogie' truck similar to that first introduced into the locomotive *Experiment* in 1832 by John B. Jervis. The *E. L. Miller* had two cylinders of 10 in. diameter, 16 in. stroke, and it weighed about 7½ tons. Baldwin, who was born in Elizabeth, New Jersey, on December 10, 1795, began life as a jeweller and silversmith. In 1825 with David Mason he set up as a machinist and soon began the construction of small stationary steam engines. With the advent of the steam railway in England, Franklin Peale, the proprietor of the Philadelphia Museum, commissioned Baldwin to make a miniature locomotive. With imperfect sketches of the engines which had taken part in the famous Rainhill trials of 1829, Baldwin made a small engine which drew two cars around a track in the Museum, and it was the success of this model which led to his receiving the order for the *Old Ironsides*. Baldwin died in 1866, by which time he had built more than 1,000 locomotives.

Prediction of the Tides

In 1833 our knowledge of the tides was very imperfect. Bernouilli and Laplace had attempted to formulate rules for prediction on theoretical grounds but without much practical success, and although several tide-tables were published annually, they differed considerably from one another. Sir John William Lubbock had for nineteen years been collecting tide observations for the Port of London, and on February 20, 1834, in a paper "On the Tides" read before the Royal Society, he included tables for the prediction of the tides at London, far more accurate than any previously available. He also described numerous observations on the influence of the wind, which is of considerable importance in limiting the accuracy with which tides can be predicted. The analysis of Lubbock's great mass of data was mainly due to the Rev. William Whewell, who introduced new mathematical methods into the problem. His results were published in a paper read before the Royal Society on January 9, 1834, "On the empirical Laws of the Tides in the Port of London, with some Reflections on the Theory".

Anniversary Meeting of the Geological Society

The anniversary meeting was held on February 21 at the Society's apartments in Somerset House; Mr. Greenough was continued president, and R. I. Murchison and H. Warburton were elected to succeed Dr. Fitton and Prof. Sedgwick, the retiring vice-presidents. It was announced that the proceeds of the Wollaston donation fund had been awarded to M. Agassiz in testimony of the high opinion entertained of his work on fossil fishes, and to encourage him in the prosecution of his important undertaking. The Society dined at the Crown and Anchor Tavern, and afterwards adjourned to their own apartments to hear the remainder of the president's anniversary address

Ashmolean Society, Oxford

At a meeting of this Society held on February 21, 1834, P Duncan, of New College, exhibited part of the contents of a mummy of a crocodile, recently presented to the museum by Mr Munro, and gave some account of crocodiles from Cuvier and other writers. Dr. Daubeny exhibited Daniell's pyrometer, and made some observations on the influence of light on animal life; and concluded by proposing the following query "Is it reasonable to suppose (with Dr Edwards) that the singular animal called the *Proteus Anguinus*, which occurs in the dark caverns of Carniola, is a reptile whose form has never been developed, bearing the same relation to some unknown species which the tadpole does to the frog?"

Agricultural and Horticultural Museums and Gardens

Agricultural Museum, Edinburgh Prof Law, the scientific teacher of agriculture in the University of Edinburgh, has long been engaged in forming, at his own private expense, an agricultural museum; and we are most happy to learn, from the Scotch newspapers, that government has lent pecuniary aid to so useful an undertaking. Whether any exhibition of the kind instituted at Stirling, and followed by Mr Lawson of Edinburgh, and Dickson of Perth, is to be combined with this museum, we have not learned, but we are most happy to see the government of the country taking an interest in such national objects We hope the time is not far distant when a sum will be advanced to complete the Thames tunnel, and another to establish the Horticultural Society's garden at Chiswick on a permanent footing If this is not done by government, we hope that, when the metropolis and its environs are put under one system of self-government, they will have a metropolitan garden, either at Chiswick, or elsewhere, worthy of the first city in the world, and open to all its citizens (J C Loudon, in the *Gardener's Magazine* of February 1834)

Brunel's Thames Tunnel

In February 1834, a collection of models of buildings and public works was on view in King William Street, West Strand, London, the most important exhibit being a model of the Thames Tunnel from Rotherhithe to Wapping. The model, which was on a scale of ¼ in to a foot, was described by the *Times* as doing great credit to the ability, ingenuity and taste of the artist and as an exceedingly accurate representation in miniature of what the tunnel would be when completed Begun in 1825, the tunnel, for which the elder Brunel was the engineer, had attracted a great deal of attention and on one occasion the Duke of Wellington said: "Of my own knowledge I can speak of the interest excited in foreign nations for the welfare and success of this undertaking, they look upon it as the greatest work of art ever contemplated". As in the case of Trevithick's tunnel of 1808, immense difficulties were encountered during its construction. In May 1827, when a distance of 544 ft. had been excavated, there was an irruption from the river This was overcome, but in January 1828 a more serious irruption occurred, which nearly cost the younger Brunel his life, and as funds were then exhausted, work ceased for the time. Various efforts were made to obtain funds from the Government for the completion of the work and the negotiations which finally proved successful were in progress when the model of 1834 was on exhibition to the public. The tunnel, which was 1,300 ft. long, 20 ft high and 35 ft. wide, was closed to the public in 1866, when it was purchased by the East London Railway Company

LONDON

Royal Society, February 8 G. SALT Experimental studies in insect parasitism. (1) Introduction and technique. (2) Superparasitism. Statistical analysis of field data relating to natural parasitism by *Collyria calcitrator*, *Ibalia leucospoides* and *Limnerium validum* shows that the parasites were not distributed at random among their hosts. A female of *Trichogramma evanescens* placed on a group of hosts can be observed to avoid ovipositing in hosts already attacked Females of *Trichogramma* are able, at least for a time, to retain their eggs rather than deposit them in parasitised hosts This restraint leads to the deposition of fewer eggs than the parasites are actually capable of laying Females of *Trichogramma* are able to distinguish between large and small hosts and, when the number of hosts is limited, lay two, three or even four eggs in some of the larger ones The hypothesis that the progeny of parasitoids are distributed at random, without reference to the previous parasitisation of the host, is untenable for the species considered MISS D E SLADDEN Transference of induced food habit from parent to offspring (1) Previous experiments with the stick-insect (*Carausius morosus*) in 1912–15 tended to indicate the inheritance of an induced food-habit With the object of testing this possibility a series of experiments was devised. In the first generation few insects took ivy at all readily, only 10 per cent at the first presentation, 32 per cent at the second, 21 per cent at the third, 12 per cent at the fourth and so on for as many as ten presentations before the whole 125 insects being tested were induced to accept ivy. These insects were then grouped according to the presentation at which ivy was taken and reared to maturity on that food-plant. In the next generation 78 per cent took ivy at the first presentation. Other insects of the second generation were tested for preference. An insect on hatching was given both privet and ivy, being required to show its preference at three successive feeds Some insects took only privet, others only ivy and yet others showed no preference These were regarded as neutral Offspring of privet-fed parents, 44 per cent privet, 35 per cent neutral, 21 per cent ivy. Offspring of ivy-fed parents, 28 per cent privet, 37 per cent neutral, 35 per cent ivy. MISS P. A CLAPHAM: Experimental studies on the transmission of gapeworm (*Syngamus trachea*) by earthworms *Eisenia fœtida*, an earthworm commonly found in contaminated soil, is an important intermediate host of *Syngamus trachea*, the common gapeworm of birds. *Lumbricus terrestris*, another earthworm, may also act as intermediate host, but is much less efficient. The third stage larva of *S. trachea*, which hatches from the egg, is ingested by the earthworm; it migrates to the muscles of the body wall, where a thin hyaline cyst is developed around it. It remains dormant in this position, undergoing no further morphological development, until the earthworm is taken in by a chicken or other suitable host The *Syngamus* larva then hatches, finds it ways to the lungs and trachea, where it settles down and grows to an adult gapeworm *Syngamus merulæ*, the gapeworm of blackbirds, has been transmitted to chickens by means of infected *Eisenia fœtida*.

Intellectual Freedom

AS years count, little more than a generation has passed since Huxley died Prof A V Hill's Huxley Memorial lecture on "The International Status and Obligations of Science" (see NATURE, Dec 23, pp 952–954), while stressing the world's debt to Huxley for his vindication of intellectual freedom, reminded us, if any reminder were needed, that since the War, in far less than a generation, indeed in a period of a little more than the last ten years, we have seen the making of a new world, the world of the dictator, in which the spirit is as alien to that of Huxley's day as was the spirit of the Middle Ages

In retrospect it is easily possible to attach too great significance to the opposition encountered by the scientific ideas propounded by Huxley and the school of thought of which he stands as the representative The nineteenth century was an age of great expansions By an almost daily experience its horizons were enlarged The extension of commerce and industry made possible by the growth of population and new markets opened up by travel, exploration and settlement, the increase of political power among the people, and the spread of education confirmed society in a dynamic attitude towards the problems of life To this attitude the concepts of an evolutionary philosophy and the scientific ideas of Darwin and Huxley were more nearly akin than the static appeal to authority of those by whom they were opposed It was an age which believed in the possibility of progress, in the possibility of a continuous and progressive amelioration in the conditions of life and above all in the potentialities of man himself Backward, barbarous and uncivilised peoples, all, it was thought, might be raised to the status of the most advanced in course of time, given education and training

To a generation which came to maturity in the latter half of the nineteenth century, freedom of thought was the natural corollary of the complete emancipation of the individual, which had been the prevailing tendency of preceding years, and was, it was then thought, the goal of future progress. The removal of disabilities due to birth, status or religion by movements, such as, for example, Catholic emancipation and the throwing open of the universities, particularly the admission of non-conformists, seemed to be the counterpart of the abrogation of authority and the freeing of inquiry in the sphere of the intellect, which had been initiated by Bacon, himself a product of the spirit of the Reformation, in the application of scientific method and experimental investigation to the problems of natural science, and of which the final stage, apparently, lay open with the acceptance of evolutionary doctrines and the annihilation of the concept of fixed species as god-created entities As in the political world the efforts of conservatism were directed towards tempering progressive measures by a compromise with established institutions which would not bar forward movement, so in matters intellectual, when once the complete verbal inspiration of the Bible was recognised to be no longer tenable, the efforts of the keenest minds among the orthodox e directed towards the reconciliation of science and religion, rather than to an endeavour to mark off a forbidden territory by chains of authority, which, it was seen, advanced thought would either pass by or overleap

This was a world of which Huxley was both a product and a formative influence He taught a public which was ripe to give hearing to his doctrine It is unnecessary to labour the point by further analysis of the complex interweave of social and intellectual movement of that day There are, however, two tendencies, or factors, to which reference may be made for their bearing on present problems These are the international status of science and the relation of science to politics, and questions of policy in connexion with social problems

On the general question of the international standing of science little need be added to the references to the position in the past which were made by Prof Hill in his address Science and learning and, in a lesser degree, art, as he showed, in the past have transcended national boundaries and have been accorded international status. On the other hand, in recent times, the free interchange of ideas which is the end and justification of the claim of science to be regarded as free of all frontiers, has been, in Great Britain at least, e form of expression of the belief in the ultimate unity and solidarity of mankind as a whole, which underlies the intellectual internationalism of the medieval church, and in the Protestant world of later times has inspired humanitarian movements such as the emancipation of the slaves and intervention on behalf of oppressed peoples on various occasions

The question of the relation of science to politics and socio-political problems opens up a field which offers opportunity for wide divergence of opinion, as is shown in the correspondence between Prof Hill and Prof. J B. S. Haldane which has appeared in our columns (see NATURE, Jan 13, pp 65–66) Prof Hill's contention that science holds a privileged position in consequence, and on the condition of, its detached attitude towards matters which are the subject of political or social controversy and partisanship is unquestionably sound in so far as it affects the objects and conditions of pure scientific research The object of the research worker is the attainment of truth, of the teacher of science the inculcation of the methods of attaining that object and the demonstration of the progress which has been made towards it In neither case must there be bias due to extraneous influence or any attempt to sway the judgment of those under instruction, whether it be a class or the wider audience of the general public, a body of opinion of increasing importance in these days of broadcasting

On the other hand, the scientific worker is a citizen, and as such it is his civic duty to bring his special knowledge to bear on the problems which present themselves to him as a member of the State Further, as a specialist he may be called in to minister to the ills of the body politic He alone has the specialised knowledge which can apply the results of research carried out in an academic atmosphere of detachment to the practical problems of life Moreover, as the State in the performance of its function of ensuring for its members the best possible conditions of life, work and even of amusement, substitutes for regulations framed by rule of thumb, legislation which is in accord with the most recent dicta of science, the aid of the man of science is invoked with greater frequency and over a wider field He may even be asked to frame a policy, or he may feel called upon of his own initiative to point out the way of future progress He becomes a propagandist in the better sense. In the earlier days of the Rothamsted Experimental Station, for example, it would on occasion have been difficult to draw the line between agricultural instruction and propaganda

To a great extent the application of scientific methods and scientific ideas to the problems of government and administration has been an outcome of the theory of State intervention, of which the wide extension is the outstanding contribution of the nineteenth century to political thought and practice It is true that on occasion science has found government departments somewhat difficult to persuade that the course of action dictated by scientific considerations was expedient or advisable. Yet on the whole, the fact that State regulation is a necessity which impinges on every side of the life of the community and affects it in multitudinous detail, in the long run has ensured that these regulations should be framed in the light of the results of scientific research Whatever may be the defects of bureaucratic government, it does afford greater opportunity for the rational application of scientific method to domestic problems, unattainable in a pure democracy, failing the Utopian condition of a scientifically educated public and an executive fully and continuously abreast of the development of science and its practical applications.

The War marked the close of an epoch—a period, in which, it has been attempted to show, the political atmosphere fostered freedom of scientific inquiry, the free interchange of scientific ideas and personnel on an international basis, and an increasing application of scientific methods and results to conditions in every department of the citizen's daily life.

From the welter which followed on the conclusion of peace, we are only now beginning to emerge, and that only in so far as the conditions on which recovery will be attempted are becoming defined Impressed by the results achieved by national discipline during the War, perhaps remembering how, at first under Bismarck's guidance and then under the Kaiser, the German States were welded into the most powerful national organisation of modern times, the foremost peoples of the world are placing themselves under the control of the organised State, consolidated on a national basis, of which the political and economic segregation is emphasised at every turn, but more particularly by tariffs, exchanges and trade balances, States in which an all-powerful emotional appeal is afforded by devotion to a political theory as in Russia, the call of race or nationality, as in Germany, or of loyalty to a leader who exercises a dictatorial power as in Italy or the United States of America.

With the merits and demerits of a political system, strictly as such, we have no concern in these columns, except in so far as it may become the subject of scientific sociological investigation. But it is of vital interest to science that what may be the relation of political theory and practice under the organised State, founded on a nationalist basis, to scientific inquiry should be clearly apprehended. The atmosphere of political freedom of Huxley's day, in which scientific inquiry grew to its full stature, has vanished. Is science to go back under a system of State control to swaddling clothes ?

To the social reformer and the scientific worker who hates the waste of life, time and energy under rule of thumb and tradition, the organised State under dictatorial power, whether wielded by a cabinet or an individual, presents many attractions. It abrogates government by the Press, and the otherwise uninstructed vote of the mass. In it the man of science rightly sees no more than an extension of the bureaucratic regime of State control which in the past has been instrumental in applying the progressive concepts of science to social amelioration No doubt future generations will rise up to call General Góring blessed, because he has decreed a reserve for the preservation of the wild animals of northern Europe, yet had his verdict gone the other way, who could now prevail ? And those who applaud the work of archæological exploration and restoration which the Duce has promoted to the glory of the Italian nation may be pardoned if they feel some qualms lest the claims of some period or subject less complimentary to the Italian genius be overlooked. Who or what is to ensure that the organised State in the exercise of its power of control shall not dictate to science what subjects may or may not be matter for inquiry, and the direction that inquiry shall take ? The Dayton trial has not yet sunk into oblivion, and to-day in Germany the whole State organisation and the fabric of society rest on a pseudo-scientific theory of Aryan supremacy, once formulated for political reasons and long ago exploded outside her national boundaries, but internally not to be questioned To conform to that illusion Germany has closed her frontiers , she has evicted some of her greatest scientific investigators, with thousands of the rank and file, content, as it has been put, that her science should lag behind that of the rest of the world, provided that it were German; and finally, in the full spirit of the Hebrew Scriptures, if repudiating them in form, she seeks to evolve a German God, barely refraining from invoking by name Wodan, the God of Battles, who has risen again.

Since the above was written, we have received the circular on the teaching of history in Germany of which a translation appears in this issue (p. 288). It is perhaps worth while to place this on record, lest it should appear that in directing attention to the danger that authority under the organised State might seek to prescribe for science the line to be taken in teaching and research, NATURE may appear to have issued a warning after the event.

There is much in the political situation of the day, even in Great Britain, which justifies Prof. Hill's fears for the future of intellectual freedom.

Physiology and Behaviour of Primates

(1) *Functional Affinities of Man, Monkeys and Apes: a Study of the Bearings of Physiology and Behaviour on the Taxonomy and Phylogeny of Lemurs, Monkeys, Apes and Man.* By Dr. S. Zuckerman. Pp. xviii+203+12 plates. (London: Kegan Paul and Co., Ltd., 1933.) 10*s*. 6*d*. net.

(2) *Behavior Mechanisms in Monkeys.* By Heinrich Klüver. (Behavior Research Fund Monographs.) Pp. xvii+387+9 plates. (Chicago: University of Chicago Press; London: Cambridge University Press, 1933.) 22*s*. net.

(1) DR. ZUCKERMAN, whose previous volume on the "Social Life of Monkeys and Apes" (1932) was favourably received, has in this new work collected together the somewhat scattered knowledge relating to the 'functional' characteristics of the various types of primates, and considered its bearings upon the classification and phylogeny of the group. He deals among other things with the mechanisms of reproduction, blood reactions, the physiology of the sense-organs, and behaviour in relation to cortical differentiation.

In general, the indications supplied by these functional characters are consistent with the orthodox view of the relationships of the primates, as expressed in the commonly accepted taxonomy of the order. They do not, however, throw any very clear light upon problems of phylogeny. Zuckerman has clearly performed a useful service in bringing together much information which is not easily accessible to the taxonomist and morphologist. The book is well documented and has a good bibliography. It is illustrated by 24 plate figures of apes, monkeys and lemurs, from photographs by F. W. Bond.

It is interesting to note that Zuckerman refers with approval to the work of St. George Mivart in the 'seventies, who in spite of his anti-Darwinian attitude expressed some very sound views on primate relationships. Mivart's contention that there is little difference in respect of mental powers between monkeys and apes is one which receives some support from recent psychological research. (2) Thus in Dr. Kluver's book on the behaviour of monkeys, we find that some species, particularly of the genus *Cebus*, can utilise tools almost as effectively as Köhler's chimpanzees. This was also the conclusion of Bierens de Haan on the basis of his experiments with *Cebus hypoleucus* (1931). Actually we do not yet know enough about the behaviour of apes and monkeys to be able to rank them in order of 'intelligence', but it is significant that the more carefully and sympathetically they are studied the more complex and adaptable their behaviour appears.

Kluver's book is a contribution of the first importance to this fascinating study. It is admirably characterised by Dr. K. S. Lashley in his introduction as follows:

> "Dr. Kluver's monograph sets a new standard for analytic studies of behaviour. He has proposed the question, Just what properties in complex sensory situations are significant for the animal's reactions? and has carried out the investigation with unique thoroughness. As a result, he presents for the first time something approaching a complete picture of the perceptual world of an animal. This perceptual organisation is surprisingly like that of man. Not only are the animals sensitive to the same physical stimuli but for them also the relational properties of the situations are the same. As with man, reactions are but little dependent upon the simple physical properties of the stimulus but rather upon abstract relations which may subsist in physically unlike situations."

These valuable conclusions as to the importance of bare relations in determining responses were obtained by the "method of equivalent stimuli".

The general problem set was to pull in one of two (or more) boxes, which were differentiated from one another by some physical characteristic, as for example weight. The monkey was first trained to pull in, say, the heavier of two boxes of given weights; when training was complete the weights of the boxes were altered throughout a wide range, and it was found that the monkey almost invariably chose the heavier of the pair quite irrespective of the absolute weights. Then the appearance of the boxes was altered in various ways, but the response to the bare relation 'heavier than' was still maintained. This type of experiment, using the pulling-in technique, was extended to many other characteristics, such as shapes and colours, and most interesting results obtained.

The investigations dealt with both New World and Old World monkeys and also with a lemur; the experiments were admirably devised and controlled, and they are reported in full detail.

Scarcely less important than the experimental results is Kluver's extremely able and thorough discussion of their theoretical bearing, and his very full and careful treatment of the general principles of interpretation of animal behaviour We agree with Lashley's opinion that this discussion is "one of the most important recent contributions to theoretical psychology".

Real progress is at last being made in the study of animal behaviour, through a combination of direct and accurate observation, simple experimentation, and careful logical analysis, independent of all preconceived theory, and Kluver's book greatly furthers this good work.

E S R

Decompositions into Fifth Powers

British Association for the Advancement of Science. Mathematical Tables Vol 3 · *Minimum Decompositions into Fifth Powers.* Prepared by Prof L E Dickson (Published under the supervision of the British Association Committee for the Calculation of Mathematical Tables) Pp vi+368 (London British Association, 1933) 10*s*

SINCE 1931, when the British Association started to publish mathematical tables in volume form, three sets of tables have appeared The first comprised tables of general utility · trigonometric, hyperbolic, exponential, gamma and other functions The second issue contained Emden functions and had therefore a less popular appeal, since the tables were designed to aid in certain astrophysical researches, and the cost of printing was undertaken by the International Astronomical Union The present (third) volume, while not perhaps of such a specialised character, deals with a subject which from its nature must interest directly but a small body of scientific workers.

By the generous bequest of Lieut.-Col. A. J. C. Cunningham, the British Association has funds available to assist in the production of tables connected with the theory of numbers The scope of application of this fund would appear to be limited on one hand by the necessity of finding suitable material, and on the other by finding research workers both willing and able to produce work of the required character. In this respect the Committee is indeed fortunate in having the opportunity to undertake the printing of vol 3, the subject of which could not more clearly come under the terms of the Cunningham bequest

The actual matter of the present table concerns the solution of the Diophantine equation:

$$x_1^5 + x_2^5 + \qquad + x_s^5 = n,$$

where n is a given integer less than 300,000 and where s is to be a minimum The method of tabulation will be apparent from the following extract:

10399	0	0	1	3		10
10406	3	2	2	0	1	11

This indicates that

$$10399 = 0 \times 2^5 + 0 \times 3^5 + 1 \times 4^5 + 3 \times 5^5.$$

Thus when $n = 10399$, $x_1 = 4$, $x_2 = x_3 = x_4 = 5$ and $s = 1 + 3 = 4$ The number 10 at the end of the first row indicates that the largest integer, 10405, which precedes the next tabular entry, 10406, requires ten fifth powers, namely, the four already given for 10399 and six units, so that

$$10405 = 6 \times 1^5 + 1 \times 4^5 + 3 \times 5^5$$

From 150,000 onwards the decompositions are omitted, the minimum number of decompositions being indicated as explained above Thereafter the actual decompositions can be readily found by trial, subtracting 9^5, 10^5, or 11^5 and consulting the previous part of the table

One purpose of a table of this character is to produce experimental data in connexion with Waring's problem (in this case for fifth powers). In this problem there are two numbers of interest, m_5 and M_5; m_5 is the smallest number such that every integer is the sum of m_5 or fewer fifth powers, and M_5 is the smallest number such that from a certain point onwards every integer is the sum of M_5 or fewer fifth powers That such numbers exist has been proved by Hilbert for the general case of *k*th powers, but their actual values for $k = 5$ is not known. It is known that $37 < M_5 < 53$, the last number being due to Hardy and Littlewood. Using the present tables, Prof Dickson has proved that all integers with fewer than 484 figures are sums of 37 or fewer fifth powers and that all integers with fewer than 1,177 figures are sums of 41 or fewer fifth powers An inspection of the table tempts one to surmise the possible existence of a number $a_5 < 15$, such that almost all integers are the sums of a_5 or fewer fifth powers

The table is reproduced photographically from typescript and is very clear The author states that the elaborate checks required more time than the construction of the table

The existence of the British Association tables might become more widely known if it were possible to have them permanently listed in a publisher's catalogue L M MILNE-THOMSON.

Recent Research in Metallurgy

The Journal of the Institute of Metals (1) Vol. 50 *Metallurgical Abstracts and Index to Volumes 48, 49 and 50 of the Journal* Pp vi+962 (2) Vol. 51 Edited by G Shaw Scott Pp. 363+28 plates. 31*s*. 6*d* (3) Vol 52 Edited by G Shaw Scott. Pp 255+50 plates. 31*s* 6*d* (London · Institute of Metals, 1933.)

(1) THIS volume contains the general and non-ferrous metallurgical abstracts which have already been published during 1932 in the monthly *Journal* These abstracts not only provide the worker in physical metallurgy with an invaluable guide to the literature of the subject, but also constitute a very useful aid to the physicist or physical chemist whose interests lie in this direction As usual, the literature has been surveyed accurately over a broad front, but whether the latter is rather too broad is open to question The Institute's desire to cater for all types of its membership can be appreciated, but considerable space is taken up by abstracts of articles which are merely recapitulations of existing knowledge and practice A noticeable omission is a list of the periodicals abstracted

Although the monthly issue of these abstracts undoubtedly constitutes a great improvement on the score of rapidity of publication, considerable delay now seems to occur in their re-issue as a single volume

(2) Some thirteen papers presented at the March 1933 meeting of the Institute of Metals are collected in this volume of proceedings, together with Prof Portevin's May lecture on "The Phenomena of Quenching and Tempering in Alloys" Prof Portevin deals in a thought-provoking manner with the general principles and mechanism of precipitation hardening due to differences of solid solubility at high and low temperatures, and shows that these phenomena, far from being exceptional, are extremely common These considerations open a new field of research in the application to existing alloys of the principles of precipitation hardening.

Three papers by N. P. Allen and his co-workers deal in a fundamental manner with the practical problems of unsoundness in ingots of copper and copper-nickel alloys The recently developed tellurium-lead alloy forms the subject of one communication, and a further paper records the effects of progressive rolling reductions on the physical properties of zinc strip Two papers deal with the electrical conductivity of aluminium wire used for transmission lines, whilst other topics include the fatigue-resisting properties of aluminium alloys at elevated temperatures and the interpretation of the tensile test with reference to lead alloys Particular mention should be made of a paper by Bradley and Jones on the re-examination of the copper-aluminium system by the X-ray powder method

(3) The autumn meeting last year constituted the twenty-fifth anniversary of the foundation of the Institute of Metals, and was appropriately held in Birmingham, the original home of the Institute This volume of proceedings contains the fourteen papers presented on this occasion, together with Mr W R Barclay's Autumn Lecture on "Twenty-Five Years' Progress in Metallurgical Plant", which is illustrated with an excellent series of photographs of melting, rolling, and auxiliary equipment Probably the most interesting of the papers is Dr Rosenhain's review, prepared at the request of the Council, of progress in non-ferrous metallurgy during the life-time of the Institute. Much metallurgical history has been made in this period, and Dr Rosenhain briefly surveys a number of developments, including the improved equilibrium diagram technique, the study of deformation and fatigue, the application of X-ray methods, and the development of light alloys and of special cutting alloys, with many of which he and his students have been intimately connected.

Research on precipitation hardening is represented by two papers, both dealing with copper-nickel-aluminium alloys, and a further contribution from Allen concerns the distribution of porosity in aluminium and copper ingots. Other papers deal with the preparation of lead alloys for microscopic examination, the protection of magnesium alloys, the annealing of copper wire and the corrosion-fatigue characteristics of an aluminium specimen consisting of two crystals. The papers and ensuing discussions testify to the value of the past twenty-five years' work of the Institute in the stimulation of the study of alloys.

L. B. H.

Short Reviews

Recent Advances in Agricultural Plant Breeding By Dr H Hunter and Dr H Martin Leake Pp x+361+16 plates (London. J and A Churchill, 1933) 15s

DURING the past generation the expansion of plant-breeding work on agricultural plants has been so rapid that it is impossible to present even a condensed comprehensive review within the limits of a single volume Recognising this, the authors have confined their attention to the results of the more important investigations which have emerged from the academic stage and have resulted in improved varieties that have passed into general use Indications are given of the general direction of progress and of some of the main problems awaiting solution

Attempted improvements are often determined by commercial requirements, which may vary not only from one country to another, but also within each country itself Further improvement in plants is relative to the environment, as soil fertility and climate, and is not an absolute condition, for example, a new variety that gives excellent results in one area, or under certain manurial treatment, may show no advantage elsewhere or under different cultural conditions The extreme difficulty is recognised of arriving at a truly homozygous unit giving a completely stable plant, and the indications adduced from practice are that stability is in reality a relative term, but that some varieties are more stable than others

Work in temperate regions is chiefly on food crops, with species and varieties long under domestication The range of sub-tropical and tropical crops is much wider, and many of them are much nearer their wild forebears, thus raising very different problems in improvement Under tropical conditions, also, environmental conditions encourage disease so much that the evolution of disease-resisting types takes precedence even of yield and quality improvement.

The survey is suggestive and its usefulness is increased by the provision of illustrations and numerous references associated with the individual crops

Geology By Prof William H Emmons, Prof George A Thiel, Prof. Clinton R Stauffer and Prof Ira S. Allison Pp xii+514 (New York. McGraw-Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd., 1932) 24s net

THE collaboration of four professors in the production of an introductory textbook of their subject must be a rare event In this present instance the experiment, if it may be called such, has been successful, for the result is a lucid and logical exposition of the principles of geology The greater part of the work deals with geological processes and is uniformly excellent. American examples are mainly employed for illustration, but the subjects are usually so magnificent that such a choice is right.

The last half a dozen chapters of the book are concerned with the origins of mountains, metamorphism, rock structures, conditions within the earth, earth history and kindred subjects Here the treatment is not quite so successful The account of the origin and structure of mountains, for example, is sketchy, and the references, especially to the Alps, distinctly inadequate. Again, the grand unity of metamorphic processes —the only guiding light in this uncharted sea—is obscured by a needless subdivision of the subject Further, the planetesimal theory of the origin of the solar system is presented without critical examination But, in spite of this, the book is certainly a good modern introduction to the subject and would be useful as a supplementary text for British students In the main it is written in a pleasing easy style that is remarkably uniform throughout the volume The illustrations, nearly five hundred in number, are well chosen and well reproduced

Basic Units in Mechanical Drawing By Prof Randolph Philip Hoelscher and Prof Arthur Beverly Mays Book 1 Pp viii+289 (New York John Wiley and Sons, Inc, London· Chapman and Hall, Ltd, 1933) 10s net

THE preface sufficiently indicates the design of the book, and the accompanying text throughout bears testimony to the realisation of that design. The authors are to be congratulated on being able to present the results of their practical experience in an eminently practical form Nor can the diagrams, which are so liberally furnished, be over-praised.

The jejune qualities so frequently apparent in books of this nature are herein totally absent If a demurring criticism is due, it is in respect to the somewhat mechanical system of lettering advocated, preferably lettering should be introduced upon a freehand mode of treatment

P L M.

Collision Processes in Gases By Dr F L Arnot (Methuen's Monographs on Physical Subjects) Pp viii+104 (London Methuen and Co, Ltd, 1933) 3s net.

THIS useful little volume deals with that group of collision phenomena in gases in which the processes may be treated as individual events. It is divided into two parts. The main section deals with collisions between electrons and atoms and the brief second part gives some account of collisions between photons and atoms, and between normal, excited and ionised atoms

The book is lucidly and critically written and may be unreservedly commended A F.

Thomas Young

By Sir Joseph Larmor, F.R.S.

It is a welcome feature of the times that interest in the great pioneers who created the science of mathematical physics in Great Britain shows signs of revival The recent publication of a biographical sketch of Thomas Young by Mr Frank Oldham[*] is an indication At the time of his decease (1829) at the age of fifty-six years, the task of collecting and editing Young's later scientific writings passed into the hands of George Peacock, Dean of Ely and Lowndean professor at Cambridge and though through pressure of business at Cambridge and Ely he took twenty years over the work, the result in two volumes on physical science, with a third on hieroglyphical research, and the indispensable standard biography as a fourth, is, or ought to be, in a proper scheme of things, one of the permanent classics of natural knowledge It reveals the editor, known as one of the introducers of the formal Continental analysis into Cambridge, as an adept critic in general Natural Philosophy of the Newtonian type as well

In those early days scientific people did not write numerous treatises, and as a result, into their work, as intended for permanence, they put their most sustained thought The nascent separate sciences had moreover then to be systematised, and they were not seldom, just as now, knocking up against mutual discrepancies that demanded both unrelaxing effort and a safe provisional judgment Even in pure theory the preparation of the immortal "Mécanique Analytique", a systematising treatise of no great length or abstruseness, built on historical foundations, occupied a long time, and is said to have so exhausted Lagrange that he had to desert mathematical science for several years We may contrast with this the stupendous achievement of Isaac Newton, who, in spite of irritations from which he was far from immune, managed under stimulus to prepare the "Principia", in part doubtless from material which already he had by him in some form, in eighteen months The formal legacy of British physical theorists of about a century and a half ago, especially in the Scottish universities, mainly developing out of their formal courses of lectures to large audiences, and thus not infrequently posthumous as in the cases of Black and Robison, produced a species of literature tending, except in the hands of masters, to be either superficial or dull The greatest and most original of all general lecture courses was Young's "Lectures of Natural Philosophy and the Mechanical Arts", over which there was certainly no delay, as the two massive and very complete yet concise quarto volumes were published (1807) at the age of thirty-four years a few years after the course was delivered

Was it the very universality of Young's range of interests that saved him from premature mental exhaustion ? One of the three volumes of the 'miscellaneous works', edited for Peacock by his friend John Leitch, is taken up with philological studies, largely exhibiting his connexion with the early history of the cardinal advance in wide fields of knowledge rendered possible by the deciphering of the Egyptian hieroglyphics, which was first brought into Young's keen attention by the problem presented by a tri-lingual inscription on the Rosetta stone. The controversy as to the rival merits of Young and his contemporary Champollion of Grenoble, who seems to have come later into the field, doubtless far more learned in the cognate Coptic and other sources, has fluctuated ever since. The writer of the biographical sketch which suggested the present notice follows Leitch's account, and also Peacock's in an independent and trenchant analysis in the "Biography" (pp 258–344), in assigning the main credit to Young but one has a feeling that in that decision they are not in the swim The claim asserted for Young on his monument in the Abbey is that he was the first to penetrate the obscurity that veiled for ages the problem of the hieroglyphics of Egypt and, however the complete final solution be apportioned, this statement appears to hold good On reference to the last edition of the "Encyclopædia Britannica" one finds the balance struck emphatically for Champollion, in agreement as is there stated with universal authority · this may be right enough so far as the general reader can know, but even a cursory inspection of Peacock's account of progress indicates that there is more that might properly be said indeed, the name of Young is not even mentioned either under the heading "Hieroglyphics" or under the personal notice of Champollion Even more remarkable, surely by one of the workings of fortune which the Greeks named Nemesis, in compensation for his supreme classical contributions to the original "Encyclopedia", the name of Young occurs only in a secondary way in the general index to the new volumes , yet one of his own most notable works is the long series of scientific biographies which he contributed with much research to the Supplement of the early publication.

Young is still perhaps popularly known mainly from the episode of his personal collisions with the youthful Brougham, who was afterwards for some time Lord Chancellor of England. The latter, then editor of the *Edinburgh Review*, from its political and literary connexions an influential organ of opinion, avenged himself for some slighting incidental criticism of his own writings, of a kind to which Young was perhaps too much addicted, and at the same time acquired for himself a unique species of scientific renown which has clung to him, by gibbeting, in eloquent and even scurrilous terms, the revival of the wave-theory of light and its brilliant developments in many directions through Young's recognition of the principle of interference of trains of waves, which ought to have been so obvious to a real student His satire is commonly held to have diverted men from any attentive consideration of the new discoveries, by discrediting their author, and so as is said managed to postpone the progress of optical science for twenty years But that is possibly ascribing to him too much credit : Young had already become and for long remained Foreign Secretary of the Royal Society, and maintained his repute with his colleagues there, though at that time they were scarcely mathematical enough to become deeply concerned in his own researches He was moreover to receive a remuneration for the copyright of his "Lectures" handsome for that time, ultimately however owing to bankruptcy unpaid : though the book was to contain a very elaborate and expensive reprint of the great memoirs that were supposed to be discredited.

[*] "Thomas Young, F R S , Philosopher and Physician " By Frank Oldham Pp. 159+2 plates. (London . Edward Arnold and Co , 1933) 6s. net.

Young's dignified rejoinder to Brougham's abuse, published as a pamphlet, is a valuable personal record of his mode of work, though the provocation by itself had scarcely called for such serious notice he complains that only one copy of it was sold, but possibly its main function may have been for private distribution to his competent scientific friends Lord Brougham himself had less equivocal merits in other directions, especially in educational zeal, after he had been ejected from political life by his temper He appears to have been prime mover in establishing the "Society for Promoting Useful Knowledge", which succeeded in engaging some of the best scientific intellect of the time in works of general interest yet precise scientific value , for example, it produced a series of biographies which have now fallen into undeserved oblivion, and even succeeded in circulating in periodical instalments, almost in modern fashion, standard treatises of the highest rank, such as De Morgan's "Differential and Integral Calculus". How far the "Encyclopædia Metropolitana", the high-water mark of the science of its time, and the ancillary more popular volumes such as Sir John Herschel's once famous "Introduction to the Study of Natural Philosophy", so helpful to the nascent inductive logic, may have been a further outcome, we may not stop to inquire Indeed the general public neglect of which Young complained must largely have been his own fault, through his persistence in anonymous publication in brief notes, in the interest as he thought of his medical practice, which would naturally detract from the attention which was his due. His speculations, as lying outside the range of the main interests of his colleagues, and of the public of the time, had appealed coldly to them · and he appears moreover to have been a silent man,—he relates in a family letter that he was stimulated by a remark at an annual meeting of the Royal Society that "no one had heard him make a speech". The resurrection of his public fame in a later generation was largely the result of a judgment opening out to a wider audience, by Helmholtz, who had first encountered his early keen *aperçus* in the course of his own activity in the physiology of vision. Helmholtz characterised him as largely misunderstood because he was too far in advance of his times, a modified version of the perhaps natural explanation that his habits of exact thought were too concise and interwoven to permit him to give explanations at length without distracting his own attention from the concatenation of his ideas He relates that his ideas on light gradually arose from study and experiment on the phenomena of waves of sound, which occupied him and mystified his neighbours during his three years residence at Emmanuel College in Cambridge, keeping terms with a view to a medical degree The customary rather silent appreciation of his matured genius by his own British school, men such as Airy and Maxwell and Rayleigh, has not been wanting.

In another episode in his unfortunately controversial career, in relation to yet another of the fundamental physical doctrines, the principles of atomic interaction in relation to capillary phenomena, the part of Brougham was played to some extent, though with amends later, by none other than the illustrious Laplace As an offset to mathematical genius and great industry, the world has been accustomed to accept, possibly to exaggerate, Laplace's propensity to annex information for his systematic treatises from where he could find it, and modify it at will, without any great scruples regarding original discoverers If he did take over Young's ideas, he made a more artistic work of them though a student with physical instincts will probably still prefer to try to absorb the wide and often sufficient simple *aperçus* of Young before passing on to the special analytical elaboration of Laplace An illustration of the contrast is that, in a domain where Laplace is perforce silent, Young's more flexible, if somewhat obscure, train of thoughts on the relation of surface tension to molecular interaction at sensible range, manages to give him a provisional estimate, lightly held however, of the diameters and range of activity of atoms, perhaps the earliest effective attempt in that direction, as Lord Rayleigh remarked, one which though real now appears in the detailed lights of modern science to be about a hundred times too small the brief systematic expansion of such estimates of atomic size, as probed in all directions at the hands of Lord Kelvin, became a remembered incident when it appeared long after. Yet though Laplace's propensity to taking new general ideas for granted, especially when not fully developed, strongly irritated Young, with his memory of previous experience at the hands of Brougham, it had not, to take a different type of instance, prevented most friendly rivalry and combined continuous co-operations for years between Laplace and Lagrange, calm amid the turbulence of the times, in establishing and confirming the very delicate amenities of the planetary system, and incidentally indicating, starting therefrom, much of the modern analytical structure of general dynamical science. The simplicity and dignity of Lagrange's character appear indeed to have placed him entirely outside the reach of priorities or envy.

Young's work collided with the dogmatism of Laplace also in another domain. A particularly attractive and engaging episode in the history of science is the friendly rivalry of Young with his youthful French contemporary Fresnel, in exploring the mysteries of double refraction by crystals, which it is a great merit of Peacock's biography to have brought out from the original letters. A sentiment relating to these problems, with which Young had wound up an earlier exhaustive classical article "Chromatics" ("Encyc Brit" 1817. 'Works', 1, 342), merits quotation as not inapplicable to cognate mystifications in the modern world of physical speculation, especially as its pessimism was so soon to be wholly dissipated:—

> "and the greatest difficulty of all, which is to assign a sufficient reason for the reflection or non-reflection of a polarized ray, will probably long remain to mortify the vanity of an ambitious philosophy, completely unresolved by any theory".

However, Laplace had proceeded to annihilate in advance both Fresnel and Young by an elaborate deduction of double refraction from the orbital dynamics of Newtonian light-corpuscles, by an application of the general Lagrangian doctrine of Least Action: a most astonishing analytical performance, which was promptly demolished with some heat by Young, by the acumen of simple direct reasoning, and in the first instance in the popular *Quarterly Review* of all places. Here again contemplative insight asserted its mastery, as regards general ideas, over merely formal algebraic development. But this remonstrance in turn betrayed Young into a characteristic depreciation (*vol. 2, p. 567, deprecated by Peacock*), with scarcely a word of recognition of the beauty of the processes, of the method of variations, Lagrange's earliest and most fruitful discovery, which has largely been the path of analytical progress in modern physical science:

> "The steps of the method are generally simple and easily understood, at least they may and ought to be rendered so: but the merit of the invention is none the less because it admits of a very ready application and because it might have occurred to a less distinguished mathematician."

There are many other indications of Young's intuitional acquaintance, often lucid and informing, with the nascent general Continental analysis, which he was even at some pains to dissemble.

About half the second volume of the "Lectures" is occupied by a catalogue of the mathematical and physical sciences of the eighteenth century, which had completely occupied its author for three years: he obviously had examined at first hand all the works of the masters, as is evidenced by the rapid remarks, often very illuminating, sometimes deprecatory of the delay in reaching concrete results, which he appends. For his instincts were Newtonian, aiming directly at a general view of the order of Nature. But though the modes of thought born out of direct wide contemplation of Nature appeared to advantage as against the mode of early translation into abstract algebra, yet the Newtonian procedure in its other aspect, inevitable in his day, of special calculations *ad hoc*, failed, at times conspicuously as Young's work was often to illustrate, in elegance and in interest even when effective in reaching a result. Such provisional procedure could never have originated the brilliant indirect algebraic analysis, going far beyond immediate objects, and opening up novel intuitional fields of thought, which had perforce to be constructed gradually, long after Newton, for the progress to minuter detail of the relations of dynamical astronomy, the most coherent and exact of the sciences and historically a pattern for them all. No such authoritative catalogue, even of the select classical works of modern science, of personal origin, is likely to appear again.
